Toronto Notes 2014

Comprehensive medical reference and review for the Medical Council of Canada Qualifying Exam Part 1 and the United States Medical Licensing Exam Step 2

30th Edition

Editors-in-Chief:
Miliana Vojvodic and Ann Young

Wherever the art of medicine is loved, there is also a love of humanity.

– Hippocrates
Thirtieth Edition

Dedicated to all  
past and present contributors  
and  
supporters of Toronto Notes  
who have made the production of the 30th Anniversary Edition possible!

The Toronto Notes is dedicated to helping fund many charitable endeavours and medical student initiatives at the University of Toronto's Faculty of Medicine. Programs that have received Toronto Notes funding include:

**Community Affairs Projects**
- Saturday Program for Inner City High School and Grade 8 students
- St. Felix Mentorship Program for Inner City children
- Parkdale Mentorship Program for Grade 10-12 students
- WoodGreen Community Centre
- Let's Talk Science
- Growing Up Healthy

**Medical School Clubs**
- Books with Wings
- Women in Medicine
- University of Toronto International Health Program
- Complementary and Alternative Medicine
- Peer Support for Students
- History of Medicine Society
- Faculty of Medicine Yearbook

**Annual Faculty Showcase Events**
- Bruce Tovee Lecture Series
- Daffydil, in support of the Canadian Cancer Society
- Earthtones Benefit Concert
- Convocation and Ceremonies
- Clerkship Luncheon

**Scholarships and Bursaries**
- Nishant Fozdar Memorial Award
- Graduating Medical Class Scholarships and Bursaries

**NOTE:**
Many of you have wondered about the *Toronto Notes* logo, which is based on the rod of Asclepius, the Greek god of medicine. The rod of Asclepius consists of a single serpent entwined around a staff. This icon symbolizes both rebirth, by way of a snake shedding its skin, and also authority, by way of the staff.

In ancient Greek mythology, Asclepius was the son of Apollo and a skilled practitioner of medicine who learned the medical arts from the centaur Chiron. Asclepius' healing abilities were so great that he was said to be able to bring back people from the dead. These powers displeased the gods, who punished Asclepius by placing him in the sky as the constellation Orphiuchus.

The rod of Asclepius is at times confused with the caduceus, or wand, of Hermes, a staff entwined with two serpents and often depicted with wings. The caduceus is often used as a symbol of medicine or medical professionals, but there is little historical basis for this symbolism.

As you may have guessed, our logo uses the rod of Asclepius that is modified to also resemble the CN Tower – our way of recognizing the university and community in which we have been privileged to learn the art and science of medicine.

Thomas O’Brien, MD  
Class of 2009  
M.D. Program, University of Toronto
Dear Readers,

As Editors-In-Chief of Toronto Notes 2014, we are proud to celebrate the 30th Anniversary Edition of the present text.

First produced in 1983 from a set of study notes drafted by medical students at the University of Toronto, Toronto Notes has grown to be one of the premier study resources for generations of medical graduates in Canada and abroad. This rich history is rooted in our commitment to publish a student-edited, comprehensive study resource to serve students across clinical rotations and in preparation for the Canadian Medical Licensing Examination (Step 1) and the United States Medical Licensing Examination (Step 2).

Over the past 29 years, our vision has not wavered. We continuously build on the feedback of our readers to enhance the features of the text, handbook and accompanying online resources. The focus of Toronto Notes 2014 is to make medical knowledge accessible and retainable by distilling information into high-quality figures, charts and helpful mnemonics. This edition features a new easy-to-view layout across all 29 chapters, with updated text-referencing icons and illustrations. In keeping with rapid advances in medical research, the text also features newly updated best practice guidelines, including recent high-impact trials for clinical practice. The accompanying Toronto Notes Handbook also offers new algorithms, flow-charts and new reference cards to serve as a high-yield and portable resource across clinical rotations. This year we are also excited to announce the launch of the first colour edition of the Toronto Notes eBook to offer our readers an enhanced mobile learning experience.

Toronto Notes 2014 is produced by Toronto Notes for Medical Students Inc., a non-for profit organization supporting various medical student initiatives including community outreach programs, medical school clubs, local charity endeavors, and student bursaries. This year we are especially proud to support the Nishant Fozdar Memorial Award. Nishant was an exceptional medical student, colleague and dear friend in the University of Toronto medical class of 2014. This annual award was established in his memory, and will be awarded to University of Toronto students who demonstrate Nishant’s many qualities, including his dedication to education and community involvement.

Throughout the production of this edition, we have benefited from the gracious help of our student colleagues as well as numerous faculty and administrators at the University of Toronto Faculty of Medicine. Our dedicated team of over 150 students, artists and faculty editors remain the cornerstone of Toronto Notes and continue to enhance the text in its’ content and clarity each year. We are grateful for our lead editors Andy Tyrell, Vicki Wang, Maria Jogova, Howard Meng, Grace Lam, Hamed Nazzari, Jieun Kim, Daniel Soong, Melini Gupta, Jeffrey Martin and Gautam Goel as well as our 2014 production managers Sheron Perera and Bailey Dyck for their tireless work and dedication to this project. We would also like to acknowledge our partners at Type & Graphics, particularly Enrica Aguilera, for their continued guidance in the production of this text. We also thank our immensely talented cover artists Karyn Ho and Catherine Kang for their innovative vision and immaculate execution of the featured mosaic cover illustration.

Finally we would like to express our deepest gratitude to all previous Editors-In-Chief of Toronto Notes. Each editorial team left their unique mark on the text and helped Toronto Notes grow into one of the most recognizable student publications in Canada. Much like the pieces in a mosaic, the product of these countless contributions have formed the 30th Anniversary Edition before us today.

On behalf of the 2014 editorial team, we wish you the best in your studies and hope that you will find Toronto Notes 2014 to be an asset to your success.

Sincerely,

Miliana Vojvodic, MSc and Ann Young, PhD
Editors-In-Chief, Toronto Notes 2014
MD Program, University of Toronto
Acknowledgements

We would like to acknowledge the exceptional work of all previous Toronto Notes (formerly MCCQE Notes) Editors-in-Chief and their editorial teams. The 30th edition of this text was made possible with their contributions.

32. Index
How to Use This Book

This book has been designed to remain as one book or to be taken apart into smaller booklets. Identify the beginning and end of a particular section, then carefully bend the pages along the perforated line next to the spine of the book. Then tear the pages out along the perforation.

The layout of Toronto Notes 2014 allows easy identification of important information. These items are indicated by icons interspersed throughout the text:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Icon Name</th>
<th>Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Icon]</td>
<td>Key Objectives</td>
<td>This icon is found next to headings in the text. It identifies key objectives and conditions as determined by the Medical Council of Canada or the National Board of Medical Examiners in the USA. If it appears beside a dark title bar, all subsequent subheadings should be considered key topics.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Clinical Pearl</td>
<td>This icon is found in sidebars of the text. It identifies concise, important information which will aid in the diagnosis or management of conditions discussed in the accompanying text.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Memory Aid</td>
<td>This icon is found in sidebars of the text. It identifies helpful mnemonic devices and other memory aids.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Clinical Flag</td>
<td>This icon is found in sidebars of the text. It indicates information or findings that require urgent management or specialist referral.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Cross-Reference</td>
<td>This icon is found in sidebars of the text. It indicates a cross-reference for information that is discussed in a separate chapter.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Evidence Based Medicine</td>
<td>This icon is found in sidebars of the text. It identifies key research studies for evidence-based clinical decision making related to topics discussed in the accompanying text.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Colour Photo Atlas</td>
<td>This icon is found next to headings in the text. It indicates topics that correspond with images found in the Colour Photo Atlas available online. (<a href="http://www.torontonotes.ca">www.torontonotes.ca</a>).</td>
</tr>
<tr>

Chapter Divisions

To aid in studying and finding relevant material quickly, each chapter is organized in the following general framework:

Basic Anatomy/Physiology Review
- features the high-yield, salient background information students are often assumed to have remembered from their early medical school education

Common Differential Diagnoses
- aims to outline a clinically useful framework to tackle the common presentations and problems faced in the area of expertise

Diagnoses
- the bulk of the book
- etiology, epidemiology, pathophysiology, clinical features, investigations, management, complications, and prognosis

Common Medications
- a quick reference section for review of medications commonly prescribed
## Common Unit Conversions

To convert from the conventional unit to the SI unit, **multiply** by conversion factor
To convert from the SI unit to the conventional unit, **divide** by conversion factor

Further information on these topics can be found in the Objectives of the Considerations of the Legal, Ethical and Organizational Aspects of the Practice of Medicine (CLEO) – which can be downloaded free of charge from the Medical Council of Canada website at http://mcc.ca/wp-content/uploads/CLEO.pdf

Canadian law applicable to medical practice varies between jurisdictions and changes over time. Criminal law is nationwide, but non-criminal (civil) law varies between provinces. This section is meant to serve only as a guide. Students and physicians should ensure that their practices conform to local and current laws.

Legal Framework

Sources of Law

<table>
<thead>
<tr>
<th>Source of Law</th>
<th>Definition</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common Law</td>
<td>Legal rules and principles that define private rights and obligations</td>
<td>Tort Law: defines breaches of civil duty owed to someone else. Contract Law: define mutually agreed upon rights and obligations that may result in award of damages if breached.</td>
</tr>
<tr>
<td>Constitution</td>
<td>Supreme law of Canada. All other laws must be consistent with constitution.</td>
<td>Canadian Charter of Rights and Freedoms is part of the constitution and guarantees the rights of life, liberty, security of the person, and equality under the law.</td>
</tr>
</tbody>
</table>

Ethical Framework

Principles of Ethics

- ethics addresses:
  1) the principles and values that help define what is morally right and wrong
  2) the rights, duties and obligations of individuals and groups
- the practice of medicine assumes there is one code of professional ethics for all doctors and that they will be held accountable by that code and its implications

Table 1. The Four Principles Approach to Medical Ethics

<table>
<thead>
<tr>
<th>Principle</th>
<th>Definition</th>
<th>In Practice Do's</th>
<th>In Practice Don't's</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomy</td>
<td>• Recognizes an individual’s right and ability to decide for themselves according to his/her beliefs and values. • Not applicable to newborns, young children, or in situations where informed consent and choice are not possible or may not be appropriate.</td>
<td>• Respect and promote an individual patient’s values and preferences in decision making to empower him or her. • Understand, appreciate, and respect a patient’s decision even if it may differ from the recommendation of the physician. • Show fidelity to incapable patient’s prior capable views if known, and treat them with worth and dignity.</td>
<td>• Doctors are not obliged, and indeed ought not, to comply with patients wishes that are illegal or might be considered to be ‘conduct unbecoming a doctor’ (unprofessional conduct, falling below the standard of care). • A patient’s autonomy may be compromised by illness; the principle of autonomy is not a trump card and must be balanced by the rest of the listed principles. • Patients are not expected to act in ways considered ‘reasonable’ or rational by others as long as they do not harm others.</td>
</tr>
</tbody>
</table>

Autonomy vs. Competence

**Autonomy:** the right that patients have to make decisions according to their beliefs and preferences.

**Competence:** the ability or capacity to make a specific decision for oneself.
Table 1. The Four Principles Approach to Medical Ethics (continued)

<table>
<thead>
<tr>
<th>Principle</th>
<th>Definition</th>
<th>In Practice Do’s</th>
<th>In Practice Don’ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beneficence</td>
<td>• The patient-based ‘best interests’ standard that combines doing good, avoiding harm, taking into account the patient’s values, beliefs, and preferences, so far as these are known</td>
<td>• Try to ensure that a treatment’s benefits outweigh its burdens</td>
<td>• Do not make a decision without a patient’s input (direct or indirect)</td>
</tr>
<tr>
<td></td>
<td>• Autonomy should be integrated with the physician’s conception of a patient’s medically-defined best interests</td>
<td>• Recommend treatment based on evidence and professional experience to patients and help them weigh the risks and benefits of various options</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The aim is to minimize harmful outcomes and maximize beneficial ones</td>
<td>• Where a patient’s capacity is compromised, physicians have more authority to act purely in the patient’s best interests as defined by the therapeutic relationship but they still ought to do so in ways informed by the patient’s known wishes and with the involvement, where possible, of the patient’s substitute decision-maker</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Paramount in situations where consent/choice is not possible or may not be appropriate</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Non-Maleficence</td>
<td>• Obligation to avoid causing harm; primum non nocere (“First, do no harm”)</td>
<td>• Efforts should be made to reduce error and adverse events and ensure patient safety</td>
<td>• Do not recommend a treatment because it will have some harm associated with it</td>
</tr>
<tr>
<td></td>
<td>• A limit condition of the Beneficence principle</td>
<td>• A key guide for all management plans</td>
<td></td>
</tr>
<tr>
<td>Justice</td>
<td>• Fair distribution of benefits and harms within a community, regardless of geography or privilege</td>
<td>• Scarce resources are distributed based on the needs of patients and the benefit they would receive from obtaining a specific resource e.g. organs for transplantation are fairly distributed if they go to those who are the most unwell, who are the most likely to survive the longest with the transplant, and who have waited the longest to receive a transplant</td>
<td>• Physicians ought to be ‘door openers’, not ‘gate-closers’, for their patients</td>
</tr>
<tr>
<td></td>
<td>• Concept of fairness: Is the patient receiving what he/she deserves – his/her fair share? Is he/she treated the same as equally situated patients? How do one set of treatment decisions impact on others?</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Respect rules of fair play and basic human rights, such as freedom from persecution and the right to have one’s interests considered and respected</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Code of Ethics

- CMA developed a Code of Ethics that acts as a common ethical framework for Canadian physicians
  - prepared by physicians for physicians and applies to physicians, residents, and medical students
  - based on the fundamental ethical principles of medicine
  - sources include the Hippocratic Oath, developments in human rights, recent bioethical discussion
  - statements are general in nature
  - CMA policy statements address specific ethical issues not mentioned by the code (e.g. abortion, transplantation, and euthanasia)
- the American Medical Association (AMA) has a Code of Medical Ethics
  - articulates the values of medicine as a profession and defines medicine’s integrity
  - source of the profession’s authority to self-regulate
  - evolving document that changes as new questions arise; AMA policy positions (“AMA Policy”) address current health care issues, the health care system, internal organizational structure, decision-making processes, and medical science and technology

The Canadian Adverse Events Study: The Incidence of Adverse Events among Hospital Patients in Canada

**Studies:** Hospital charts randomly selected and reviewed in four randomly selected Canadian hospitals for the fiscal year 2000. Patients: 6,174 patient charts sampled, 3,745 eligible charts (>18 yr of age; nonpsychiatric, nondiabetic, minimum 24 h admission). Results: AE rate was 7.5% per 100 hospital admissions (95% CI 5.7-9.3). Highly preventable AEs occurred in 36.9% of patients with AEs (95% CI 32.0-41.3%) and death occurred in 20.0% (95% CI 17.3%-23.8%). An estimated 1521 additional hospital days were associated with AEs. Patients with AEs were significantly older than those without (mean age and standard deviation) 64.9 [16.3] v. 62.0 [18.4] yr; p = 0.016. Men and women experienced equal rates of AEs.

Conclusions: The overall incidence rate of AEs of 7.5% suggests that, of the almost 2.5 million annual hospital admissions in Canada similar to the type studied, about 185,000 are associated with an AE and close to 70,000 of these are potentially preventable.

Adverse Event (AE)

An unintended injury or complication from health care management resulting in disability, death or prolonged hospital stay.

The CMA Code of Ethics is a quasi-legal standard for physicians. If the law sets a minimal moral standard for doctors, the Code ratchets up these standards.
Doctor-Patient Relationship

**Ethical Basis**

- A partnership based on the physician providing expert opinion, information, options, and interventions that allows the patient to make informed choices about his/her health care
- Within this relationship, the doctor and patient share the goals of positive health outcomes, good communication, honesty, flexibility, sensitivity, informed consent, and respect
- This relationship has the potential to be unequal due to a power difference
  - Patients are ill and lack medical expertise
  - Physicians possess specialized medical knowledge and skills
  - Physicians are in a fiduciary relationship with their patients
- Due to the nature of the doctor-patient relationship, the physician will:
  - Place the best interests of the patient first
  - Establish a relationship of trust with the patient
  - Follow through on undertakings made to the patient in good faith
- The physician will accept or refuse patients requesting care:
  - Without consideration of race, gender, age, sexual orientation, financial means, religion or nationality
  - Without arbitrary exclusion of any particular group of patients, such as those known to be difficult or affiliated with serious disease
  - Except in emergency situations, in which case care must be rendered
- Once having accepted a patient into care, the physician may terminate the relationship provided:
  - It is not an emergency
  - After a reasonable period of time (usually a month) for the patient to find alternate care
  - Adequate notice (usually an explanatory letter by registered mail) has been given to the patient
  - There are other options to find ‘medically necessary care’ (in other words, in smaller communities with fewer options for care, there may need to be some flexibility in cessation of care)
- The reason for termination ought to be ‘failure of trust’
- The physician will not exploit the doctor-patient relationship for personal advantage – for sexual, financial, academic or other purposes
- The physician will disclose limitations to the patient where personal beliefs or inclinations limit the treatment the physician is able to offer
- The physician will maintain and respect professional boundaries at all times
  - Including physical, emotional, and sexual boundaries
  - Regarding treatment of themselves, their families, and friends

**Legal Basis**

- Duties and rights defined partly by:
  - Tort law that allows patients to recover damages for wrongful acts committed against them; the most important are:
    - A. Negligence: breach of a legal duty of care (in tort) which results in damage
    - Legal finding, not a medical one
    - Physicians may be found negligent when the following four conditions are met:
      1. The physician owed a duty of care to the patient (the existence of a doctor-patient relationship generally suffices)
      2. The duty of care was breached (e.g. by failure to provide the standard of care)
      - The standard of care is one that would reasonably be expected under similar circumstances of an ordinary, prudent physician of the same training, experience, and specialization
      3. The patient was injured or harmed
      4. The harm or injury was caused by the breach of the duty of care
    - Errors of judgment are not necessarily negligent
    - Making the wrong diagnosis is not negligent if a reasonable doctor might have made the same mistake in the same circumstances
    - Failure to reconsider the diagnosis if the patient does not respond to treatment may be negligent
    - Physicians can be held liable for the negligent actions of their employees or other individuals they are supervising
  - B. Battery: the application of force to a person’s body without their consent
  - Contractual rights and obligations that if breached may result in the award of damages
  - Fiduciary duty of physicians to their patients (i.e. to act in their best interest)

In situations in which it would be more difficult for a patient to find alternate “medically necessary care”, the physician may need to exhibit some flexibility in cessation of care.

"Failure of trust" situations include “double-doctoring” on the part of the patient and patient threats of violence.

CPSO Policy: Treating Self and Family Members
Physicians will not diagnose or treat themselves or family members except for minor conditions or in emergencies and then only if no other physician is readily available.

CPSO Policy: Ending the Physician-Patient Relationship
Discontinuing services that are needed is an act of professional misconduct unless done by patient request, alternative services are arranged, or adequate notice has been given.

Dealing with Controversial and Ethical Issues in Practice
- Discuss in a non-judgmental manner
- Ensure patients have full access to relevant and necessary information
- Identify if certain options lie outside of your moral boundaries and refer to another physician if appropriate
- Consult with appropriate ethics committees or boards
- Protect freedom of moral choice for students or trainees

Source: MCC CLEO Objectives 1998
Consent and Capacity

- the autonomous authorization of a medical intervention by a patient
- applies to acceptance and refusal of treatment

Ethical Principles Underlying Consent and Capacity
- usually the principle of respect for patient autonomy overrides the principle of beneficence
- where a patient cannot make an autonomous decision (i.e. incapable), it is the duty of the SDM (or the physician in an emergency) to act on the patient's known prior wishes or, failing that, to act in the patient's best interests
- there is a duty to discover, if possible, what the patient would have wanted when capable
- central to determining best interests is understanding the patient's values, beliefs, and cultural or religious background
- more recently expressed wishes take priority over remote ones
- patient wishes may be verbal or written
- patients found incapable to make a specific decision should still be involved in that decision as much as possible
- agreement or disagreement with medical advice does not determine findings of capacity/ incapacity
- however, patients opting for care that puts them at risk of serious harm that most people would want to avoid should have their capacity carefully assessed

Consent

Obtaining Legal Consent
- consent of the patient must be obtained before any medical intervention is provided; consent can be:
  - verbal or written, although written is usually preferred
  - a signed consent form is only evidence of consent – it does not replace the process for obtaining valid consent (see Figure 1)
  - what matters is what the patient understands and appreciates, not what the signed consent form states
  - implied (e.g. a patient holding out their arm for an immunization) or expressed
- consent is an ongoing process and can be withdrawn or changed after it is given, unless stopping a procedure would put the patient at risk of serious harm
- Health Care Consent Act (of Ontario) covers consent to treatment, admission to a facility, and personal assistance services (e.g. home care)

Four Basic Requirements of Valid Consent
1. Voluntary
   - consent must be given free of coercion or pressure (e.g. from parents or other family members who might exert ‘undue influence’)
   - the physician must not deliberately mislead the patient about the proposed treatment
2. Capable
   - the patient must be able to understand and appreciate the nature and effect of the proposed treatment
3. Specific
   - the consent provided is specific to the procedure being proposed and to the provider who will carry out the procedure (i.e. the patient must be informed if students will be involved in providing the treatment)
4. Informed
   - sufficient information and time must be provided to allow the patient to make choices in accordance with their wishes. This information should include:
     - the nature of the treatment or investigation proposed and its expected effects
     - all significant risks and special or unusual risks
     - alternative treatments or investigations and their anticipated effects and significant risks
     - the consequences of declining treatment
     - risks that are common sense need not be disclosed (i.e. bruising after venipuncture)
     - answers to any questions the patient may have
- the reasonable person test – the physician must provide all information that would be needed “by a reasonable person in the patient's position” to be able to make a decision
- disclose common adverse events (>1/200 chance of occurrence) and serious risks (e.g. death) even if remote
- it is the physician's responsibility to make reasonable attempts to ensure that the patient understands the information
- physicians should not withhold information about a legitimate therapeutic option based on personal conscience (e.g. not discussing the option of emergency contraception)

CPSO Policy Consent

Obtaining valid consent before carrying out medical, therapeutic and diagnostic procedures has long been recognized as an elementary step in fulfilling the doctor’s obligations to the patient.
Exceptions to Consent

1. Emergencies
   - treatment can be provided without consent where a patient is experiencing severe suffering, or where a delay in treatment would lead to serious harm or death and consent cannot be obtained from the patient or their substitute decision maker (SDM)
   - emergency treatment should not violate a prior expressed wish of the patient (e.g. a signed Jehovah’s Witness card)
   - if patient is incapable, MD must document reasons for incapacity and why situation is emergent
   - patients have a right to challenge a finding of incapacity as it removes their decision-making ability
   - if a SDM is not available, MD can treat without consent until the SDM is available or the situation is no longer emergent

2. Legislation
   - Mental Health legislation allows for:
     - the detention of patients without their consent
     - psychiatric outpatients may be required to adhere to a care plan in accordance with Community Treatment Orders (see Psychiatry, PS7)
   - Public Health legislation allows medical officers of health to detain, examine, and treat patients without their consent (e.g. a patient with TB refusing to take medication) to prevent transmission of communicable diseases (see Population Health and Epidemiology, PH19)

3. Special Situations
   - public health emergencies (e.g. an epidemic or communicable disease treatment)
   - warrant for information by police

Consequences of Failure to Obtain Valid Consent

- treatment without consent is battery (an offense in tort), even if the treatment is life-saving (excluding situations outlined in exceptions section above)
- treatment of a patient on the basis of poorly informed consent may constitute negligence, also an offense in tort
- the onus of proof that valid consent was not obtained rests with the plaintiff (usually the patient)

Capacity

- capacity is the ability to:
  - understand information relevant to a treatment decision
  - appreciate the reasonably foreseeable consequences of a decision or lack of a decision
  - capacity is specific for each decision (e.g. a person may be capable to consent to having a chest x-ray, but not for a bronchoscopy)
  - capacity can change over time (e.g. temporary incapacity secondary to delirium)
  - most Canadian jurisdictions distinguish capacity to make health care decisions from capacity to make financial decisions; a patient may be deemed capable of one, but not the other
  - a person is presumed capable unless there is good evidence to the contrary
  - capable patients are entitled to make their own decisions
  - capable patients can refuse treatment even if it leads to serious harm or death; however, decisions that put patients at risk of serious harm or death require careful scrutiny
  - capacity assessments must be conducted by a physician and, if appropriate, in consultation with other health care professionals (e.g. another physician, a mental health nurse)
  - clinical capacity assessment may include:
    - specific capacity assessment (i.e. capacity specific to the decision at hand)
      1. effective disclosure of information and evaluation of patient's reason for decision
      2. understanding of:
        - his/her condition
        - the nature of the proposed treatment
        - alternatives to the treatment
        - the consequences of accepting and rejecting the treatment
        - the risks and benefits of the various options (test: can the patient recite back what you have disclosed?)
      3. for the appreciation needed for decision making capacity, a person must:
        - acknowledge the condition that affects him/herself
        - be able to assess how the various options would affect him or her
        - be able to reach a decision and adhere to it, and make a choice, not based primarily upon delusional belief (test: are their beliefs responsive to evidence?)
    - general impressions
    - input from psychiatrists, neurologists, etc.
  - employ “Aid to Capacity Evaluation” (see Table 2)
Table 2. Aid to Capacity Evaluation

| Ability to understand the medical problem |
| Ability to understand the proposed treatment |
| Ability to understand the alternatives (if any) to the proposed treatment |
| Ability to understand the option of refusing treatment or of it being withheld or withdrawn |
| Ability to appreciate the reasonably foreseeable consequences of accepting the proposed treatment |
| Ability to appreciate the reasonably foreseeable consequences of refusing the proposed treatment |
| Ability to make a decision that is not substantially based on delusions or depression |

Adapted from Etchells, et al. 1996

- A decision of incapacity may warrant further assessment by psychiatrist(s), legal review boards (e.g. in Ontario, the Consent and Capacity Review Board), or the courts
- Judicial review is open to patients if found incapable

Treatment of the Incapable Patient in a Non-Emergent Situation
- Obtain informed consent from SDM
- An incapable patient can only be detained against his/her will to receive treatment if he/she meets criteria for certification under the Mental Health Act. In such a situation:
  - Document assessment in chart
  - Notify patient of assessment using appropriate mental health form(s) (Form 42 in Ontario)
  - Notify rights advisor

Substitute Decision Makers (SDMs)
- SDM must follow the following principles when giving informed consent:
  - Act in accordance with wishes previously expressed by the patient while capable
  - If wishes unknown, act in the patient’s best interest, taking the following into account:
    1. Values and beliefs held by the patient while capable
    2. Whether well-being is likely to improve with vs. without treatment
    3. Whether the expected benefit outweighs the risk of harm
    4. Whether a less intrusive treatment would be as beneficial as the one proposed
- The final decision of the SDM may and should be challenged by the MD if the MD believes the SDM is not abiding by the above principles

Figure 1. Ontario consent flowchart

Most provinces have legislated hierarchies for SDMs; the hierarchy in Ontario is:
- Legally appointed guardian
- Appointed attorney for personal care, if a power of attorney confers authority for treatment consent (see Powers of Attorney, ELOAM8)
- Representative appointed by the Consent and Capacity Board
- Spouse or partner
- Child (age 16 or older) or parent (unless the parent has only a right of access)
- Parent with only a right of access
- Sibling
- Other relative(s)
- Public guardian and trustee
INSTRUCTIONAL ADVANCE DIRECTIVES

• allow patients to exert control over their care once they are no longer capable
• the patient sets out their decisions about future health care, including who they would allow to make treatment decisions on their behalf and what types of interventions they would want
• takes effect once the patient is incapable with respect to treatment decisions
• in Ontario, a person can appoint a power of attorney for personal care to carry out his/her advance directives
• patients should be encouraged to review these documents with their family and physicians and to reevaluate them often to ensure they are current with their wishes

POWERS OF ATTORNEY

• all Guardians and Attorneys have fiduciary duties for the dependent person

Definitions

• Power of Attorney for Personal Care
  • a legal document in which one person gives another the authority to make personal care decisions (health care, nutrition, shelter, clothing, hygiene, safety) on their behalf if they become mentally incapable

• Guardian of the Person
  • someone who is appointed by the Court to make decisions on behalf of an incapable person in some or all areas of personal care, in the absence of a POA for personal care

• Continuing Power of Attorney for Property
  • a legal document in which a person gives another the legal authority to make decisions about their finances if they become unable to make those decisions

• Guardian of Property
  • someone who is appointed by the Public Guardian and Trustee or the Courts to look after an incapable person's property or finances

• Public Guardian and Trustee
  • acts as a SDM of last resort on behalf of mentally incapable people who do not have another individual to act on their behalf

• Pediatric Aspects of Capacity Covered by the HCCA, Ontario
  • no age of consent; consent depends on patient's decision-making capacity
  • QC has a specific age of consent, but common law and case law deem underage legal minors capable, allowing them to make their own choices; all other provinces and territories do not have an age of consent
  • infants and children are assumed to lack mature decision-making capacity for consent but they should still be involved (i.e. be provided with information appropriate to their comprehension level)
  • adolescents are usually treated as adults
  • preferably, assent should still be obtained from patient, even if not capable of giving consent
  • in the event that the physician believes the SDM is not acting in the child's best interest, an appeal must be made to the local child welfare authorities
  • under normal circumstances, parents have right of access to the child's medical record

Confidentiality and Reporting Requirements

• a full and open exchange of information between patient and physician is central to a therapeutic relationship
• privacy is a right of patients (which they may forego), while confidentiality is a duty of doctors (which they must respect barring patient consent or the requirements of the law)
• if inappropriate breached by a doctor, he/she can be sanctioned by the hospital, by the court or by his or her regulatory authority
• based on the ethical principal of patient autonomy, patients have the right to:
  • control their own information
  • expect information concerning them will receive proper protection from unauthorized access by others (see Privacy of Medical Records, ELOAM9)
• confidentiality may be ethically and legally breached in certain circumstances, e.g. the threat of harm to others
• unlike the solicitor-client privilege, there is no ‘physician-patient privilege’ by which a physician, even a psychiatrist, can promise the patient absolute confidentiality
• physicians should seek advice from their local health authority or the Canadian Medical Protective Association (CMPA) before disclosing HIV status of a patient to someone else
• many jurisdictions make mandatory not only the reporting of serious communicable diseases (e.g. HIV), but also the reporting of those who harbour the agent of the communicable disease
• physicians failing to abide by such regulations could be subject to professional or civil actions
• the legal duty to maintain patient confidentiality is imposed by provincial health information legislation and precedent-setting cases in the common law
Statutory Reporting Obligations
- legislation has defined specific instances where public interest overrides the patient right to confidentiality; varies by province, but may include:
  1. suspected child abuse or neglect – report to local child welfare authorities (e.g. Children’s Aid Society)
  2. fitness to drive a vehicle or fly an airplane – report to provincial Ministry of Transportation (see Geriatric Medicine, GM10)
  3. communicable diseases – report to local public health authority (see Population and Epidemiology, PH25)
  4. improper conduct of other physicians or health professionals – report to college or regulatory body of the health professional (sexual impropriety by physicians is required reporting in some provinces)
  5. vital statistics must be reported; reporting varies by province (in Ontario, births are required to be reported within 30 d to Office of Registrar General or local municipality; death certificates must be completed by a MD then forwarded to municipal authorities)
  6. reporting to coroners (see Physician Responsibilities Regarding Death, ELOAM13)
- physicians who fail to report in these situations are subject to prosecution and penalty, and may be liable if a third party has been harmed

Duty to Protect/Warn
- the physician has a duty to protect the public from a known dangerous patient; this may involve taking appropriate clinical action (e.g. involuntary detainment of violent patients for clinical assessment), informing the police, or warning the potential victim(s) if a patient expresses an intent to harm
- first established by a Supreme Court of California decision in 1976; supported by Canadian courts
- obliged by the CMA Code of Ethics and recognized by some provincial/territorial regulatory authorities
- concerns of breaching confidentiality should not prevent the MD from exercising the duty to protect; however, the disclosed information should not exceed that required to protect others
- applies in a situation where:
  1. there is a clear risk to identifiable person(s);
  2. there is a risk of serious bodily harm or death; and
  3. the danger is imminent (i.e. more likely to occur than not)

Disclosure for Legal Proceedings
- disclosure of health records can be compelled by a court order, warrant, or subpoena

Privacy of Medical Records
- privacy of health information is protected by professional codes of ethics, provincial and federal legislation, the Canadian Charter of Rights and Freedoms, and the fiduciary duty
- the federal government created the Personal Information Protection and Electronic Documents Act (PIPEDA), which established principles for the collection, use, and disclosure of information that is part of commercial activity (e.g. physician practices, pharmacies, private labs)
- PIPEDA has been superseded by provincial legislation in many provinces, such as the Ontario Personal Health Information Protection Act, which applies more specifically to health information

Duties of Physicians with Regards to the Privacy of Health Information
- inform patients of information-handling practices through various means (e.g. posting notices, brochures and pamphlets, and/or through discussions with patients)
- obtain the patient’s expressed consent to disclose information to third parties
  - under Ontario privacy legislation, the patient’s expressed consent need not be obtained to share information between health care team members involved in the “circle of care.” However, the patient may withdraw consent for this sharing of information and may put parts of the chart in a “lock box”
- provide the patient with access to their entire medical record; exceptions include instances where there is potential for serious harm to the patient or a third party
- provide secure storage of information and implement measures to limit access to patient records
- ensure proper destruction of information that is no longer necessary
Physician Competence and Professional Conduct

CanMEDS Competencies (Ethical/Policy Statement)
- a framework of professional competencies established by the Medical Council of Canada (MCC) as objectives for the Medical Council of Canada Qualifying Exam (MCCQE)
- further information on MCC objectives can be found at www.mcc.ca

1. Communicator
- display sensitivity to people of all ages, races, cultures, religions, sexual orientations, and genders
- accept or refuse patients without consideration of age, race, culture, religion, sexual orientation, and gender
- understand the variation in values and morals and their impact on approaches to care and decision-making
- elicit patients' beliefs, concerns, and expectations about their illness
- conduct patient-centered interviews, ensure patient comprehension

2. Collaborator
- respect all members of the health care team
- identify the roles and competencies of each member, and delegate tasks appropriately
- consult other physicians and health care professionals effectively and appropriately
- consult with patients and families regarding continuing care plans
- be able to outline co-ordination of services (e.g. Public Health, Home Care, Social Services, Workers' Compensation, Children's Aid Society, etc.)

3. Health Advocate
- identify determinants of health:
  - biological (e.g. genes, impact of lifestyle)
  - physical (e.g. food, shelter, working conditions)
  - social (education, employment, culture, access to care)
- influence public health and health policy to protect, maintain, and promote the health of individuals and the community

4. Manager
- meet regulatory requirements in an office practice (e.g. medical record-keeping, narcotic control, infection control, etc.)
- be prudent in utilization of health care resources, based on anticipated cost-benefit balance
- regulate work schedule such that time is available for continuing education

5. Professional
- maintain standards of excellence in clinical care and ethical conduct
- exhibit appropriate personal and interpersonal behaviour
- enhance clinical competence through lifelong learning
- accept responsibility for personal actions
- do not exploit the physician-patient relationship for personal advantage (e.g. financial, academic)

6. Scholar
- commitment to critical appraisal, constructive skepticism
- participate in the learning of peers and others (e.g. students, health care professionals, patients)

7. Medical Expert
- integration of all CanMEDS competencies to provide patient centred care
- combination of knowledge, clinical skills and judgment, procedural skills and professional behaviour for effective patient care

Legal Considerations
- the competence and conduct of physicians is legally regulated in certain respects to protect patients and society
- physicians are legally required to maintain a license with the appropriate authority
- physicians must ensure that patients have access to continuous on-call coverage and are never abandoned
- sexual conduct with patients, even when consented to by the patient, is a serious matter that can lead to criminal, civil, and disciplinary action
  - sexual conduct includes intercourse, undue touching, inappropriate reference to sexual matters, sexual jokes, and physician presence when capable patients undress or dress
- in some situations physicians may have a personal relationship with a patient provided a year has passed since the last therapeutic contact
Truth Telling

Ethical Basis
- helps to promote and maintain a trusting physician-patient relationship
- patients have a right to be told important information that physicians have regarding their care
- enables patients to make informed decisions about health care and their lives

Legal Basis
- required for valid patient consent (see Consent and Capacity, ELOAM5)
  - goal is to disclose information that a reasonable person in the patient's position would need in order to make an informed decision ("standard of disclosure")
- withholding information can be a breach of fiduciary duty and duty of care
- obtaining consent on the basis of misleading information can be seen as negligent

Evidence about Truth Telling
- most patients want to know what is wrong with them
- although many patients want to protect family members from bad news, they themselves would want to be informed in the same situation
- truth telling improves compliance and health outcomes
- informed patients are more satisfied with their care
- negative consequences of truth telling can include decreased emotional well-being, anxiety, worry, social stigmatization, and loss of insurability

Challenges in Truth Telling

Medical Error
- medical error may be defined as 'preventable adverse events' caused by the patient's medical care and not the patient's underlying illness. Some errors may be identified before they harm the patient, so not all error is truly 'adverse'
- many jurisdictions and professional associations expect and require physicians to disclose medical error; that is, any event that harms or threatens to harm patients must be disclosed to the patient or the patient's family and reported to the appropriate health authorities
- physicians should disclose to patients the occurrence of adverse events or errors caused by medical management, but should not suggest that they resulted from negligence because:
  - a) negligence is a legal determination
  - b) error is not equal to negligence (see Negligence, ELOAM4)
- disclosure allows the injured patient to seek appropriate corrective treatment promptly
- physicians should avoid simple attributions as to cause and sole responsibility of others or oneself
- physicians should offer apologies or empathic expressions of regret ("I wish things had turned out differently") as these can increase trust and are not admissions of guilt or liability
- Apology Acts across Canada protect apologies, both as expressions of regret and admissions of responsibility, from being used as evidence of liability and negligence

Breaking Bad News
- 'bad news' may be any information that reveals conditions or illnesses threatening the patient's sense of well-being
- caution patients in advance of serious tests about possible bad findings
- give warnings of impending bad news (see sidebar for example) and make sure you provide time for the patient
- poorly done disclosure may be as harmful as non-disclosure
- truth-telling may be a process requiring multiple visits
- adequate support should be provided along with the disclosure of difficult news
- SPIKES protocol was developed to facilitate "breaking bad news"
Arguments Against Truth Telling
- may go against certain cultural norms and expectations
- may lead to patient harm and increased anxiety
- 10-20% of patients prefer not to be informed
- medical uncertainty may result in the disclosure of uncertain or inaccurate information

Exceptions to Truth Telling
- patients may 'waive' the right to know: patient declines information that would normally be disclosed
- a patient may waive their right to know the truth about their situation when
  - the patient clearly declines to be informed
  - there is a strong cultural component that should be respected and acknowledged
  - the patient may wish others to be informed and make the medical decisions for him/her
  - the more weighty the consequences for the patient from non-disclosure, the more carefully one must consider the right to ignorance
- 'Emergencies': an urgent need to treat may legitimately delay full disclosure; the presumption is that most people would want such treatment and the appropriate SDM cannot be found
- 'Therapeutic privilege'
  - withholding information by the clinician in the belief that disclosure of the information would itself lead to severe anxiety, psychological distress or physical harm to the patient
  - clinicians should avoid invoking therapeutic privilege due to its paternalistic overtones and is a defense of non-disclosure that is rarely accepted anymore. It is often not the truth that is unpalatable; it is how it is conveyed that can harm the patient

Research Ethics
- involves the systematic analysis of ethical dilemmas arising during research involving human subjects to ensure that:
  - study participants are protected
  - clinical research is conducted to serve the interests of the participants and/or society as a whole
- major ethical dilemmas arise when a physician's obligation to the patient comes into conflict with other obligations and incentives
- any exceptions to disclosure for therapeutic consent do not apply in an experimental situation

Table 3. Ethical Principles for Research Involving Human Subjects
- Patient’s participation in research should not put him/her at a known or probable disadvantage with respect to medical care (i.e. cannot deny participants in research ‘known effective care’, for example, unethical to randomize some patients who are depressed to a placebo arm)
- Participant’s voluntary and informed choice is usually required
- Consent may not be required in special circumstances: chart reviews without patient contact; emergency situations for which there is no accepted or helpful standard of care and the proposed intervention is not likely to cause more harm than such patients already face
- Access to the treatment that is considered standard
  - Placebo-controlled trials are generally acceptable where patients still receive the standard of care and are informed about the placebo arm and what that entails
- Must employ a scientifically valid design to answer the research question
  - Scientific rigour ensured via peer review, expert opinion
- Must demonstrate sufficient value to justify the risk posed to participants
- Must be conducted honestly (i.e. carried out as stated in the approved protocol)
- Findings must be reported promptly and accurately without exaggeration, to allow practicing clinicians to draw reasonable conclusions
- Patients must not be enticed into risky research by the lure of money and investigators must not trade the interests of patients for disproportionate recompense by a sponsor; both participants and investigators are due fair recompense for their time and efforts
- Any significant interventional trial ought to have a data safety monitoring board that is independent of the sponsor and can ensure safety of the ongoing trial

Physician-Industry Relations
- health care delivery in Canada involves collaboration between physicians and the pharmaceutical and health supply industries in the areas of research, education, and clinical evaluation packages (e.g. product samples)
- physicians have a responsibility to ensure that their participation in such collaborative efforts is in keeping with their duties to their patients and society
- gifts or free products from the pharmaceutical industry are inappropriate
  - sponsorship for travel and fees for conference attendance may be accepted only where the physician is a conference presenter and not just in attendance
- physicians receiving such sponsorship must disclose this at presentations or in written articles

Guiding Principles for Research Ethics
- Respect for persons: informed consent
- Beneficence: harm vs. benefit
- Justice: avoid exploitation/unjustified exclusion

Informed Consent for Research
- Purpose of study
- Sum of funding
- Name and probability of harm and benefits
- Nature of physician’s participation including compensation

CMA and CPSO Guidelines for Ethically Appropriate Physician-Industry Relations:
- The primary goal should be the advancement of the health of Canadians
- Relationships should be guided by the CMA Code of Ethics
- The physician’s primary obligation is to the patient
- Physicians should avoid any self-interest in their prescribing and referral practices
- Physicians should always maintain professional autonomy, independence, and commitment to the scientific method

The AMA Code of Medical Ethics has a number of opinions on “Practice Matters” including “Industry representatives in clinical settings,” “Financial incentives and the practice of medicine,” and “Gifts to physicians from industry,” (see http://www.ama-assn.org/ama/pub/physician-resources/medical-ethics/code-medical-ethics.shtml).
**Physician Responsibilities Regarding Death**

- physicians are required by law to complete a medical certificate of death unless the coroner needs notification; failure to report death is a criminal offence

**Role of the Coroner**

- *Coroner's Act* (specific to Ontario, similar in other provinces) requires physicians to notify a coroner or police officer if death occurs:
  - due to violence, negligence, misconduct, misadventure, or malpractice
  - during pregnancy or is attributable to pregnancy
  - suddenly and unexpectedly
  - from disease which was not treated by a legally qualified medical practitioner
  - from any cause other than disease
  - under suspicious circumstances
- coroner investigates these deaths, as well as deaths that occur in psychiatric institutions, jails, foster homes, nursing homes, hospitals to which a person was transferred from a facility, institution or home, etc.
- in consultation with forensic pathologists and other specialists, the coroner establishes:
  - the identity of the deceased
  - where and when the death occurred
  - the medical cause of death
  - the means of death (i.e. natural, accidental, suicide, homicide or undetermined)
- coroners do not make decisions regarding criminality or legal responsibility

**Palliative and End-of-Life Care**

- focus of care is comfort and respect for person nearing death and maximizing quality of life for patient, family, loved ones
- appropriate for any patient at any stage of a life-threatening illness
- may occur in a hospital, hospice, in the community or at home
- often an interdisciplinary team of caregivers
- addresses the medical, psychosocial, and spiritual dimensions of care

**Euthanasia and Physician-Assisted Suicide**

- euthanasia: a deliberate act undertaken by one person with the intention of ending the life of another person to relieve that person's suffering where the act is the cause of death
- physician-assisted suicide: the act of intentionally killing oneself with the assistance of a physician who deliberately provides the knowledge and/or the means
- ethical issues and arguments:
  - right to make autonomous choices about the time and manner of own death
  - belief that there is no ethical difference between the acts of euthanasia/assisted suicide and foregoing life-sustaining treatments
  - belief that these acts benefit terminally ill patients by relieving suffering
  - patient autonomy has limits
  - death should be the consequence of the morally justified withdrawal of life-sustaining treatments only in cases where there is a fatal underlying condition, and it is the condition (not the withdrawal of treatment) that causes death
- the use of palliative sedation with opioids in end-of-life care, knowing that death may occur as an unintended consequence (principle of double effect) is distinguished from euthanasia and assisted suicide where death is the primary intent
- the appropriate withdrawal of life-support is distinguished from euthanasia and assisted suicide as it is seen as allowing the underlying disease to take its 'natural course'
- despite all this, refusals of care by the patient that may lead to death ought to be carefully explored by the physician to rule out any ‘reversible factors’ (such as depression, pain, loneliness, isolation) that may be hindering authentic choice
- law
  - Canada: euthanasia and physician-assisted suicide are punishable offences under the Criminal Code of Canada
  - United States: euthanasia is punishable under general homicide laws; Oregon, Washington, and Montana are the only states to have enacted legislation allowing physicians to actively assist patients who wish to end their lives
Reproductive and Sexual Health Law and Ethics

Maternal-Fetal Relationship
- in general, maternal and fetal interests align
- in some situations a conflict between maternal autonomy and the best interests of the fetus may arise

Ethical Issues and Arguments
- principle of reproductive freedom: women have the right to make their own reproductive choices
- coercion of a woman to accept efforts to promote fetal well-being is an unacceptable infringement of her personal autonomy

Legal Issues and Arguments
- law: upholds a woman’s right to life, liberty, and security of person and does not recognize fetal rights
  - if a woman is competent and refuses medical advice, her decision must be respected even if the fetus will suffer
  - the fetus does not have legal rights until it is born alive and with complete delivery from the body of the woman
- Royal Commission on New Reproductive Technologies recommendations:
  - medical treatment must never be imposed upon a competent pregnant woman against her wishes
  - no law should be used to confine a pregnant woman in the interest of her fetus
  - the conduct of a pregnant woman in relation to her fetus should not be criminalized
  - child welfare should never be used to control a woman’s behaviour during pregnancy
  - civil liability should never be imposed upon a woman for harm done to her fetus during pregnancy
- examples of implications
  - a woman is permitted to refuse HIV testing during pregnancy, even if vertical transmission to fetus results
  - a woman is permitted to refuse Caesarean section in labour that is not progressing, despite evidence of fetal distress

Advanced Reproductive Technologies (ART)
- includes non-coital insemination, hormonal ovarian stimulation, and in vitro fertilization (IVF)
- ethical issues and arguments
  - donor anonymity vs. child-centred reproduction (i.e. knowledge about genetic medical history)
  - preimplantation genetic testing for diagnosis before pregnancy
  - lack of sufficient data regarding efficacy and complications to provide the full disclosure needed for truly informed consent
  - use of new techniques without patients appreciating their experimental nature
  - embryo status – the Supreme Court of Canada maintains that fetuses are “unique” but not persons under law; this view would likely apply to embryos as well
  - access to ART
    - private vs. public funding
    - social factors limiting access to ART (e.g. same-sex couples)
  - against the ‘commercialization’ of reproduction; e.g. payment of gamete donors is currently illegal in Canada
  - however, no regulations as yet means the ART Act is not being enforced; caught in the legal web as to whether such regulations are a provincial or federal responsibility

Fetal Tissue
- pluripotent stem cells have been derived from human embryonic and fetal tissue
- potential uses of stem cells in research:
  - studying human development and factors that direct cell specialization
  - evaluating drugs for efficacy and safety in human models
  - cell therapy: using stem cells grown in vitro to repair or replace degenerated/destroyed/malignant tissues (e.g. Parkinson’s disease)
  - genetic treatment aimed at altering somatic cells (i.e. myocardial or immunological cells) is acceptable and ongoing
  - genetic treatment aimed at altering germ cells is prohibited in Canada and elsewhere
  - embryo research is permitted up to 14 d post-fertilization
  - embryos created for reproductive purposes that are no longer required may be used
  - gamete providers must give free and informed consent for research use
  - no commercial transactions in the creation and use of the embryos is permitted

The fetus does not have legal rights until it is born alive and with complete delivery from the body of the woman.

Once outside the mother’s body, the neonate becomes a member of society with all the rights and protections other vulnerable persons receive.
- Non-treatment of a neonate born alive is only acceptable if <22 wk gestational age (GA)
- 23-25 wk GA: treatment should be a consensual decision between physician and parents
- 25 wk GA and more: neonate should receive full treatment unless major anomalies or conditions incompatible with life are present
Source: Paed Child Health 2012;443

Advanced Reproductive Technologies: Ethically Appropriate Actions
- Educate patients and address contributors to infertility (e.g. stress, alcohol, medications, etc.)
- Investigate and treat underlying health problems causing infertility
- Wait at least 1 yr before initiating treatment with ART (exceptions – advanced age or specific indicators of infertility)
- Educate and prepare patients for potential negative outcomes of ART

Surrogate mothers cannot be paid or offered compensation beyond a reimbursement of their expenses.
Source: Assisted Human Reproduction Act

No one under age 18 can donate sperm or eggs, except for the purpose of creating a child that the donor plans to raise themselves (example: young patients receiving radiation therapy for cancer that may cause infertility).
Source: Semen Regulations of the Food and Drug Act

The CMA remains neutral on the issue of embryonic stem cell research.
creation of embryos solely for research purposes is prohibited
human cloning is strictly prohibited
• risks of coercion must be minimized:
  • may not pressure fertility treatment team to generate more embryos than necessary
  • only discuss option of using fetal tissue for research after free and informed choice to have a therapeutic abortion has been made
  • physicians responsible for fertility treatment may not be part of a stem cell research team

Induced Abortion
• CMA definition of induced abortion: the active termination of a pregnancy before fetal viability
  • fetal viability: fetus >500 g, or >20 wk gestational age
• CMA policy on induced abortion:
  • induced abortion should not be used as an alternative to contraception
  • counselling on contraception must be readily available
  • full and immediate counselling services must be provided in the event of unwanted pregnancy
  • there should be no delay in the provision of abortion services
  • no patient should be compelled to have a pregnancy terminated
  • physicians should not be compelled to participate in abortion – if morally opposed, the physician should inform the patient so she may consult another physician
  • no discrimination should be directed towards either physicians who do not perform or assist at induced abortions or physicians who do
  • induced abortion should be uniformly available to all women in Canada and health care insurance should cover all the costs (N.B. the upper limit of gestational age for which coverage is provided varies between provinces)
  • elective termination of pregnancy after fetal viability may be indicated under exceptional circumstances
• ethical and legal issues and arguments:
  • according to common law, the rights of a fetus are not equal to those of a human being
  • no law currently regulates abortion in Canada – it is a woman's medical decision to be made in consultation with whom she wishes; no mandatory role for spouse/family
  • 2nd and even 3rd trimester abortions are not illegal in Canada, but are usually only carried out when there are serious risks to the woman's health or if the fetus has died in utero or has major malformations (e.g. anencephaly)

Prenatal/Antenatal Genetic Testing
• uses:
  • confirm a clinical diagnosis
  • detect genetic predisposition to a disease
  • allows preventative steps to be taken and helps patient prepare for the future
  • give parents the option to terminate a pregnancy or begin early treatment
• ethical dilemmas arise because of the nature of genetic information:
  • it has individual and familial implications
  • it pertains to future disease
  • it often identifies disorders for which there are no effective treatments or preventive steps
  • also can be used to identify the sex of the fetus leading to termination of pregnancy if the fetus is of the unwanted sex; this is considered inappropriate by some but is entirely legal as a woman can request an abortion for any reason
• ethical issues and arguments:
  • obtaining informed consent is difficult due to the complexity of genetic information
  • doctor's duty to maintain confidentiality vs. duty to warn family members
  • risk of social discrimination (e.g. insurance) and psychological harm
• law:
  • no current specific legislation exists
  • testing requires informed consent
  • no standard of care exists for clinical genetics but physicians are legally obligated to inform patients that prenatal testing exists and is available
  • breach of confidentiality – duty to warn family members
  • only acceptable if can likely prevent serious harm, such as if treatment or prevention is available (e.g. familial adenomatous polyposis)

Organization of Health Care in Canada
• one federal, three territorial, and ten provincial systems
• federal system provides care to Aboriginal groups, the RCMP, and the armed forces
• financed by both the public (70%) and private (30%) sectors
• each provincial plan must cover all medically necessary health services delivered in hospitals and by physicians; may choose to cover services such as home care and prescription drugs
• non-insured health services and fees are either covered by private insurance or by the individual
• workers’ compensation funds cover treatment for work-related injuries and diseases
Legal Foundation

The legal foundation of the Canadian health system is based on two constitutional documents:
1. **Constitution Act** (1867): deals primarily with the jurisdictional power between federal and provincial governments
2. **The Canadian Charter of Rights and Freedoms** (1982): does not guarantee a right to health care but, given government's decision to finance health care, they are constitutionally obliged to do so consistently with the rights and freedoms outlined in the Charter (including the right to equality, physician's mobility rights, etc.)

And two statutes:
1. **Canada Health Act** (1984): outlines the national terms and conditions that provincial health systems must meet in order to receive federal transfer payments
2. **Canada Health and Social Transfer Act** (1996): federal government gives provinces a single grant for health care, social programs, and post-secondary education; division of resources at provinces' discretion

History

1867  **British North America Act** (now **Constitution Act**) establishes Canada as a confederacy
   - government has minimal role in health care at this time
   - "establishment, maintenance, and management of hospitals" under provincial jurisdiction

1947  Saskatchewan introduces universal hospital insurance
   - based on taxes and premiums
   - other provinces follow

1957  Federal government passes **Hospital Insurance and Diagnostic Services Act**
   - provinces with universal hospital insurance receives federal funds
   - federal government pays for approximately 50% of insured services

1962  Saskatchewan implements universal medical care insurance
   - physician services included

1965  **Royal Commission on Health Services** (**Hall Commission**) recommends federal leadership and financial support with provincial government operation

1966  **Medical Care Act** passed by federal government
   - federal government contribution maintained at 50% on average, with poorer provinces receiving more funds
   - medical insurance must be comprehensive, portable, universal, and publicly administered

1977  **Established Programs Financing Act** passed by federal government
   - federal government gives "tax points" to provinces by reducing federal taxes and allowing provinces to collect more
   - funding no longer tied to direct services → federal influence wanes
   - provinces bear greater costs and impose restrictions on physicians
   - physicians respond with "extra-billing"; patients pay a supplementary fee

1984  **Canada Health Act** passed by federal government
   - replaced **Medical Care Act** and **Hospital Insurance and Diagnostic Services Act**
   - extra-billing banned by new fifth criterion: Accessibility

1996  **Canada Health and Social Transfer Act** passed by federal government
   - federal government gives provinces a single grant for health care, social programs, and post-secondary education; division of resources at provinces' discretion

1999  **Social Union Framework Agreement** signed by the Prime Minister and all Premiers and territorial leaders except Quebec
   - federal and provincial/territorial governments vow to concentrate their efforts to modernize Canadian social policy

2001  **Kirby and Romanow Commissions** appointed
   **Kirby Commission** (final report, October 2002)
   - one-member committee of the Senate: examined history of health care system in Canada, pressures and constraints of current health care system, role of federal government, and health care systems in foreign jurisdictions
   **Romanow Commission** (final report, November 2002)
   - one-member royal commission (former Saskatchewan Premier Roy Romanow) appointed by the Prime Minister to inquire into and undertake dialogue with Canadians on the future of Canada's public health care system
2003  *First Ministers' Accord on Health Care Renewal* signed  
- First Ministers agreed on an action plan to improve access to quality care for all Canadians and to prepare an annual public report on primary and home care  
- First Health Council (composed of government and expert/public representatives) appointed to improve accountability in the health care system

2004  *First Ministers' Meeting on the Future of Health Care* produces a 10-yr plan  
- priorities include reductions in waiting times, development of a national pharmacare plan, and primary care reform

2005  *Chaoulli v. Quebec*, Supreme Court of Canada Decision  
- ruled that Quebec's banning of private insurance would be unconstitutional under the Quebec Charter of Rights, given that patients do not have access to those services under the public system in a timely way  
- Quebec government was given one year to respond

2011  First progress report by the Health Council reviews progress towards 2004 First Ministers' 10 yr plan  
- significant reductions in wait times for specific areas (such as cancer, joint replacement and sight restoration) while these reductions may have inadvertently caused increases in wait times of other services  
- despite large investments into electronic medical records (EMRs), Canada continues to have very low uptake, ranking last in the Commonwealth Fund International Health Policy survey, with use of only 37% use by primary care physicians  
- little progress in creating a national strategy for equitable access to pharmaceuticals; however, there has been some success in increasing pharmacists’ scope of practice, reducing generic drugs costs and implementing drug info systems

Federal Government announces that it will not renew *2004 First Ministers' Accord on Health Care Renewal*  
- increases in funding to provinces at 6% per annum until the 2016-2017 fiscal year, from then onwards, increases tied to nominal GDP at a minimum of 3% per annum

2012  Second progress report by the Health Council reviews progress towards 2004 First Ministers' 10 yr plan  
- funding is sufficient; however, more innovation is needed including incentivizing through models of remuneration  
- 46 recommendations were made to address the lack of progress in prevention, access to primary-care physicians, long-term, respite and palliative care services, wait-time benchmarks, accountability, IT, Aboriginal health and more

2013  Federal Government announces that it will stop funding the Health Council of Canada in 2014  
- the council (born in 2004) will close in 2014 leaving no other independent national body to assess the performance of the Canadian health care system

2014  Expiry of current *10 Year Health Care Funding Agreement* between Federal and Provincial governments

### Key Principles of the Canada Health Act

1. Public Administration  
   - provincial health insurance programs must be administered by public authorities
2. Comprehensiveness  
   - provincial health insurance programs must cover all necessary diagnostic, physician, and hospital services
3. Universality  
   - all eligible residents must be entitled to health care services
4. Portability  
   - emergency health services must be available to Canadians who are outside their home province, paid for by the home province
5. Accessibility  
   - user fees, charges, or other obstructions to insured health care services are not permitted

The federal government can reduce its contributions to provinces that violate the key principles of the Canada Health Act.

**Principles of Canada Health Act**  
- Public Administration  
- Comprehensiveness  
- Universality  
- Portability  
- Accessibility
Health Care Expenditure and Delivery in Canada

- projected total health care expenditure in 2009 was $182.1 billion, 11.9% of the GDP, approx. $4,363 USD per capita (Canadian Institute of Health Information)
- 2009 Canadian health care expenditure as a percentage of GDP ranked 6 out of 29 for Organization for Economic Cooperation and Development (OECD) member nations (Canadian Institute of Health Information)
- 70.9% of health care spending came from public sector sources in 2009 as compared to 47.7% in the US
- in 2006 there were 2.1 physicians per 1000 population, ranking 26th out of OECD member countries

Delivery of Health Care

- hospital services in Canada are publicly funded but delivered through private, not-for-profit institutions owned and operated by communities, religious organizations, and regional health authorities
- this differs from other countries, such as the US (a mix of public and private funding, as well as private-for-profit and private not-for-profit delivery) and the UK (primarily public funding and delivery)

Ethical Considerations in Resource Allocation and Physicians’ Role

- the distribution of goods and services to programs and people
- physicians have the duty to inform patients about therapeutic options even if they are not available
- distributive justice: physicians must make health care resources available to patients in a manner which is fair and equitable, without bias or discrimination
  - need and benefit are morally relevant criteria for resource allocation
  - gender, sexual orientation, religion, level of education or age alone are morally irrelevant criteria
- ethical dilemmas that arise when deciding how best to allocate resources
- fair chances versus best outcome: favouring best outcome vs. giving all patients fair access to limited resources (e.g. transplant list prioritization)
- priorities problem: how much priority should the sickest patients receive?
- aggregation problem: modest benefits to many vs. significant benefits to few
- democracy problem: when to rely on a fair democratic process to arrive at a decision
- guidelines for appropriately allocating resources
- the physician’s primary obligation is to protect and promote the welfare and best interests of his or her patients
- choose interventions known to be beneficial on the basis of evidence of effectiveness
- seek the tests or treatments that will accomplish the diagnostic or therapeutic goal for the least cost
- advocate for one’s patients but avoid manipulating the system to gain unfair advantage for them
- resolve conflicting claims for scarce resources justly, on the basis of morally relevant criteria such as need and benefit, using fair and publicly defensible procedures
- inform patients of the impact of cost constraints on care, but in a sensitive way
- seek resolution of unacceptable shortages at the level of hospital management or government

Payments for Care at Private For-Profit and Private Not-For-Profit Hospitals: A Systematic Review and Meta-analysis
CMAJ 2004;170:1817-1824
Meta-analysis of 8 US observational studies involving more than 350,000 patients. Concluded that care provided by private for-profit hospitals was more expensive (Relative payments for care = 1.19; 95% CI = 1.07-1.33; p = 0.001). If half of Canadian hospitals were converted to private for-profit institutions, an extra $3.6 billion would be paid annually.
Role of the Provincial Licensing Authorities

- the medical profession in Canada self-regulates under the authority of provincial legislation;
- physicians in each province are self-regulated by a licensing authority (e.g. College of Physicians and Surgeons of Ontario, the CPSO); membership is mandatory to practice in that province;
- self-regulation is based on the premise that the licensing authority must act first and foremost in the interest of the public;
- licensing authority functions include:
  - provincial licensing authorities provide non-transferable licensure to physicians
  - issuing non-transferable licenses allow doctors to practice only in that province
  - maintaining ethical, legal, and competency standards and developing policies to guide doctors
  - investigating complaints against doctors
  - disciplining doctors guilty of professional misconduct or incompetence
  - at times of license investiture and renewal, physicians must disclose if they have a condition (such as HIV positivity or drug addiction or other illness that may impact their ability to practice safely)
- in an evolving area of responsibility, physicians may be required to report colleagues who may be a hazard to patients (e.g. the inebriated colleague)

Licensure and Certification

- the Medical Council of Canada (MCC) certifies physicians
  - certification is known as the Licentiate of the MCC (LMCC)
  - LMCC is acquired by passing the MCC Qualifying Examination Parts I and II
- the Royal College of Physicians and Surgeons of Canada (RCPSC) certifies specialists who complete an accredited residency program and pass the appropriate exam
  - voluntary membership of RCPSC is designated FRCPC or FRCSC (Fellow of the Royal College of Physicians/Surgeons of Canada)
- the College of Family Physicians of Canada (CFPC) certifies family physicians who complete an accredited residency program and pass the Certification Examination in Family Medicine
- the RCPSC and CFPC are responsible for monitoring ongoing continuing medical education (CME) and professional development

Role of Professional Associations

- membership in a provincial or national association is voluntary
- provincial medical associations represent the economic and professional interests of doctors
- the Canadian Medical Association (CMA) is a national association that provides leadership to doctors and advocates for access to high quality health care in Canada
- the CMA represents physician and population concerns at the national level, while the provincial medical associations negotiate fee and benefit schedules with provincial governments
- medical residents are represented nationally by the Canadian Association of Interns and Residents, and provincially by Provincial Housestaff Organizations, which uphold the economic and professional interests of residents
- medical students are represented at their universities by student societies; these bodies collectively form the Canadian Federation of Medical Students; francophone medical schools participate in the Federation of Quebec Medical Student Societies
- the Canadian Medical Protective Association (CMPA), a physician-run organization, is a voluntary insurance association that protects the integrity of member physicians by providing legal defense against allegations of malpractice or negligence and by providing risk management and educational programs, and general advice

The US Health Care System

- the United States health care system is more market-based than the Canadian system
- it is funded and delivered by a mixture of the public, private, and voluntary sectors; private-for-profit is the prevailing method of delivery
- public funding is derived from taxes raised at both the federal and state government levels
History

1850 Franklin Health Insurance Company of Massachusetts
- offers accident insurance to cover injuries acquired during railroad or steamboat travel
- informal "sickness insurance" evolved from this to cover different injuries or diseases

1901 American Medical Association established as the national organization of state and local medical groups

1929 Baylor Plan developed
- created by Dr. Justin Ford Kimball to ensure that teachers could pay their medical bills
- teachers pay 50 cents/month in exchange for guarantee of medical services for 21 days

1930s More hospitals adopt medical insurance plans as per the Baylor Plan
- emergence of private, commercial, health insurance as a service of life insurance companies

1939 Community hospitals work together to create health care plans
- American Hospital Association (AHA) uses the term “Blue Cross” to describe health care plans that meet their standards
- emergence of prepaid plans covering physician and surgeon services

1940s and 1950s
- employee benefit plans increase in number with more comprehensive health care insurance packages
- companies compete for employees using the proposed health care plan
- reason why workplace is currently main source of health care insurance

1946 Blue Shield created and represents physician sponsored health care plans

1954 Social Security coverage begins to include disability benefits

1960 Blue Cross becomes the official designation for AHA health care plans

1965 Medicare and Medicaid programs introduced government funded health care plans

1971 Blue Cross and Blue Shield merge into one company

1970s and 1980s
- emergence of Health Maintenance Organizations (HMOs)
- HMOs offer managed care plans: health care packages that are provided by an HMO approved network of health care providers

1993 Universal health care system proposed but rejected by congress

1996 Mental Health Parity Act passed
- invoked to decrease discrimination in health care coverage for mental health illnesses
- aggregate annual and lifetime limits for mental health services must match aggregate annual and lifetime limits for medical and surgical services

1996 Health Insurance Portability and Accountability Act passed
- Title 1: Health Care Access, Portability, and Renewability
  - provides protection of health care coverage to employees and their families if they change or lose their job
- Title 2: Preventing Health Care Fraud and Abuse; Administrative Simplification; Medical Liability Reform
  - addresses and establishes national standards for electronic health care transactions and security and privacy of health data

1997 State Children’s Health Insurance Program (SCHIP) created
- states extend health coverage to uninsured children

1999 Ticket to Work and Work Incentives Improvement Act
- enables people with disabilities to be employed without affecting their Medicaid or Medicare coverage

2010 Affordable Care Act
- reform to health care to improve access to affordable health coverage and creates regulations on activities of private health insurance providers
Health Care Expenditure and Delivery in the US

- health care spending in the US represents a large economic sector
  - health care comprises over 17.4% of the gross domestic product (GDP) (highest in the OECD), amounting to $7960 USD per capita in 2009
  - one advantage is the widespread availability of technology – the US has 4 times as many MRI machines per capita than Canada
- the US scores poorly on some indicators of population health, with a life expectancy below the OECD average and infant mortality above the OECD average. Possible factors that account for this discrepancy are:
  - poor health of large uninsured population
  - high cost of health care administration
  - the provision of inefficient high-cost, high-intensity care
    - the higher-spending regions in the US do not provide any better quality of care, access to care, health outcomes or satisfaction with care when compared to the lower-spending regions
- the US has the highest level of obesity of all OECD nations at 34.3%; this has major implications for future health care spending

Access to Health Services

- 70% of Americans under the age of 65 have private health insurance, either employer-sponsored or individually purchased; 12% receive health care through public health insurance; 18%, mainly the poor, have no health insurance
- access to publicly funded health services occurs primarily through two programs, Medicare and Medicaid, which were created by the 1965 Social Security Act
- other federal government-funded health programs include the Military Health Services System, the Veterans Affairs Health Services System, the Indian Health Service, and the Prison Health Service

Table 4. Medicare and Medicaid Program Information

<table>
<thead>
<tr>
<th></th>
<th>Medicare</th>
<th>Medicaid</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Eligibility</strong></td>
<td>People over the age of 65</td>
<td>People who receive funds through social assistance programs</td>
</tr>
<tr>
<td></td>
<td>People with end stage renal disease</td>
<td>Pregnant women</td>
</tr>
<tr>
<td></td>
<td>People of any age meeting the Medicare definition of disability</td>
<td>People with developmental disabilities</td>
</tr>
<tr>
<td><strong>Coverage</strong></td>
<td>Basic &quot;Part A&quot; providing inpatient hospital care, home care, limited skilled nursing facility care, and hospice care</td>
<td>Basic coverage involves inpatient and outpatient hospital care, laboratory and x-ray services, skilled nursing care, home care, physician services, dental services, and family planning</td>
</tr>
<tr>
<td></td>
<td>Supplemental “Part B” covers outpatient physician and clinic services, and requires payment of a further monthly fee</td>
<td>Financing for Medicaid is provided jointly by the federal and state governments, and program details vary greatly between states</td>
</tr>
<tr>
<td><strong>Co-payment</strong></td>
<td>To help pay for out-of-pocket expenditures, and to cover many of the services not insured by Medicare, the majority of Medicare beneficiaries buy supplemental private health insurance</td>
<td>States may impose deductibles, coinsurance, or co-payments on some Medicaid recipients for certain services</td>
</tr>
</tbody>
</table>

Health Care Reform

- Patient Protection and Affordable Care Act and the Health Care and Education Reconciliation Act of 2010 are federal statutes signed into law in March 2010 that include a number of new health care provisions to be implemented over 8 yr
  - expand Medicaid eligibility, provide subsidies for insurance premiums and incentives for businesses to provide health care benefits, prohibit denial of coverage/claims for pre-existing conditions, and establish health-insurance exchanges
  - costs are offset by a number of health care related taxes, including a tax penalty for citizens with no health insurance (low income persons are exempt)

A1 Anesthesia

Toronto Notes 2014
**Anesthesia Basics**

### Types of Anesthesia

- **general**
  - general anesthesia (GA)
  - total IV anesthesia (TIVA)
- **regional**
  - spinal, epidural
  - peripheral nerve block
  - IV regional
- **local**
  - local infiltration
  - topical
- **sedation**
  - monitored anesthesia care
  - note that different types of anesthesia can be combined (e.g. general + regional)

### Pre-Operative Assessment

- to identify the patient's medical and surgical issues
- to allow for the arrangement of further investigations, consultations and treatments for patients not yet optimized
- to plan and consent for anesthetic techniques

### History and Physical

#### History

- indication for surgery
- surgical/anesthetic Hx: previous anesthetics/complications, previous intubations, medications, drug allergies
- PMHx:
  - CNS: seizures, strokes, raised ICP, spinal disease
  - CVS: CAD, MI, CHF, HTN, valvular disease, dysrhythmias, peripheral vascular disease (PVD), conditions requiring endocarditis prophylaxis, exercise tolerance, CCS class, NYHA class (see Cardiology and Cardiovascular Surgery, C31 for NYHA classification)
  - respiratory: smoking, asthma, COPD, recent upper respiratory tract infection, sleep apnea
  - GI: GERD, liver disease
  - renal: insufficiency, dialysis, chronic kidney disease
  - hematologic: anemia, coagulopathies, blood dyscrasias
  - MSK: conditions associated with difficult intubations – arthriitis (e.g. rheumatoid arthritis), cervical tumours, cervical infections/abscesses, trauma to cervical spine, previous cervical spine surgery, Down syndrome, scleroderma, obesity, conditions affecting neuromuscular junction (e.g. myasthenia gravis)
  - endocrine: diabetes, thyroid disorders, adrenal disorders
  - other: morbid obesity, pregnancy, ethanol/other drug use
- FHx: malignant hyperthermia, atypical cholinesterase (pseudocholinesterase), other abnormal drug/anesthetic reactions

#### Physical Examination

- examination of organ systems
  - focused physical exam of the CNS, CVS and respiratory systems
  - general assessment of nutrition, hydration and mental status
  - pre-existing motor and sensory deficits
- oropharynx and airway assessment to determine the likelihood of difficult intubation
  - no single test is specific or sensitive – all aid in determining the ease of intubation
  - ability to assume “sniffing position” – upper cervical spine extension, lower cervical spine flexion, previous cervical spine surgery
  - Mallampati classification (Figure 1)
  - "3-2-1 rule"
    - thyromental distance (the distance of the lower mandible in the midline from the mentum to the thyroid notch); <3 finger breadths (<6 cm) is associated with difficult intubation
    - mouth opening (<2 finger breadths is associated with difficult intubation)
    - anterior jaw subluxation (<1 finger breadth is associated with difficult intubation)
  - tongue size
  - dentition, dental appliances/prosthetic caps – must inform patients of the rare possibility of damage
  - nasal passage patency (if planning nasotracheal intubation)
- examination of anatomical sites relevant to lines and blocks
  - bony landmarks and suitability of anatomy for regional anesthesia (if relevant)
  - sites for IV, central venous pressure (CVP) and pulmonary artery (PA) catheters
Pre-Operative Investigations

Fasting Guidelines

Fasting Guidelines Prior to Surgery (Canadian Anesthesiologists’ Society)
- **8 hours** after a meal that includes meat, fried or fatty foods
- **6 hours** after a light meal (such as toast or crackers) or after ingestion of infant formula or nonhuman milk
- **4 hours** after ingestion of breast milk or Jello
- **2 hours** after clear fluids (water, black coffee, tea, carbonated beverages, juice without pulp)

American Society of Anesthesiology (ASA) Classification

- common classification of physical status at the time of surgery
- a gross predictor of overall outcome, NOT used as stratification for anesthetic risk (mortality rates)
- **ASA 1**: a healthy, fit patient
- **ASA 2**: a patient with mild systemic disease
  - e.g. controlled type 2 diabetes mellitus (DM), controlled essential HTN, obesity, smoker
- **ASA 3**: a patient with severe systemic disease that limits activity
  - e.g. stable CAD, COPD, DM, obesity
- **ASA 4**: a patient with incapacitating disease that is a constant threat to life
  - e.g. unstable CAD, renal failure, acute respiratory failure

Impact of Anesthesia Management Characteristics on Severe Morbidity and Mortality

Anesth 2005;102:257-268

Study: Case-control study of patients undergoing anesthesia.
 Patients: 807 cases and 883 controls were analyzed among a cohort of 869,483 patients undergoing anesthesia between 1995-1997. Cases were defined as patients who either remained comatose or died within 24 h of receiving anesthesia. Controls were defined as patients who neither remained comatose nor died within 24 h of receiving anesthesia.

Intervention: General, regional or combined anesthesia to patients undergoing a surgical procedure.

Main Outcome: Coma or death within 24 h of receiving anesthesia.

Results: The incidence of 24 h postoperative death was 8.8 per 10,000 anesthetics (95% CI, 8.2-9.5) and the incidence of coma was 0.5 (95% CI, 0.3-0.6). Anesthesia management risk factors that were associated with a decreased risk of morbidity and mortality were equipment check with protocol and documentation, directly available anesthesiologist with no change during anesthesia, 2 persons present at emergence of anesthesia, reversal of muscle relaxation and postoperative pain medication.
• ASA 5: a moribund patient not expected to survive 24 h without surgery
  e.g. ruptured abdominal aortic aneurysm (AAA), head trauma with increased ICP
• ASA 6: declared brain dead, a patient whose organs are being removed for donation purposes
  for emergency operations, add the letter E after classification (e.g. ASA 3E)

Pre-Operative Optimization

• in general, any fluid and/or electrolyte imbalance should be corrected prior to elective surgery

Medications

• pay particular attention to cardiac and respiratory medications, opioids and drugs with many side effects and interactions
• pre-operative medications to consider
  • prophylaxis
    • risk of GE reflux: sodium citrate 30 mL PO or ranitidine 150-300 mg PO or metoclopramide 10 mg PO 30 min to 1 h pre-op
    • risk of infective endocarditis, GI/GU interventions: antibiotics
    • risk of adrenal suppression: steroid coverage
    • consider benzodiazepines for the anxious patient
    • bronchodilators (COPD, asthma)
    • nitroglycerin and β-blockers (CAD risk factors)
• pre-operative medications to stop
  • oral hypoglycemics: stop on morning of surgery
  • antidepressants: stop on morning of surgery
  • ACE inhibitors and angiotension receptor blockers: stop on morning of surgery
  • warfarin (consider bridging with heparin), anti-platelet agents (e.g. clopidogrel)
• pre-operative medication to adjust
  • insulin (consider insulin/dextrose infusion), prednisone, bronchodilators

Hypertension

• mild to moderate HTN is not an independent risk factor for peri-operative cardiovascular complications
• target sBP <180 mmHg, dBP <110 mmHg
• assess for end-organ damage and treat accordingly

Coronary Artery Disease (CAD)

• ACC/AHA Guidelines (2007) recommend postponing elective surgery 4-6 wk following an MI
• this period carries an increased risk of reinfarction/death
  • ≤3 mo after MI – 37% patients may reinfarct
  • 3-6 mo after MI – 15%
  • >6 mo after MI – risk remains constant at 5%
• if operative procedure is essential and cannot be delayed, invasive intra- and post-operative ICU monitoring reduces the risk to 6%, 2% and 1% respectively for the above time periods
• mortality with peri-operative MI is 20-50%
• initiation of peri-operative β-blockade previously advocated; currently, some recent studies have suggested an increased risk of stroke
  • β-blockade should be continued if already started
  • initiate β-blockade if inducible ischemia, CAD or multiple cardiac risk factors and undergoing high risk surgery
  • consider initiating and optimizing β-blockade if CAD or multiple cardiac risk factors and undergoing intermediate risk surgery

Endocrine Disorders

• diabetes mellitus
  • hypoglycemia
    • caused by drugs and surgical stresses and masked by anesthesia
    • appropriate use of dextrose/insulin infusion and blood glucose monitoring
  • end organ damage: be aware of damage to CVS, renal and nervous systems, including autonomic neuropathy

Effects of Extended-Release Metoprolol Succinate in Patients Undergoing Non-Cardiac Surgery (POISE Trial): A Randomized Controlled Trial
Lancet 2008;371:1839-1847
Purpose: To investigate the role of β-blockers (metoprolol) peri-operatively in patients with known vascular disease undergoing non-cardiac surgery.
Methods: Patients from 190 centres in 23 countries were eligible if they were age >45, undergoing non-cardiac surgery and were known to have significant vascular disease. Patients were randomized to either the metoprolol group or placebo. Participants received metoprolol (or placebo) 100 mg 2-4 h prior to surgery, 6 h after surgery, and then 20 mg daily for 30 d. The primary endpoint was a composite of cardiovascular death, non-fatal myocardial infarction and non-fatal cardiac arrest. Analysis was by intention to treat.
Results: 8351 patients were recruited into the study, with 8331 completing the 30 d course. Use of metoprolol was found to significantly reduce the risk of cardiovascular death, non-fatal MI or non-fatal cardiac arrest vs. placebo (hazard ratio 0.84, p<0.05) but significantly increased the rate of stroke (hazard ratio 2.17, p<0.01) and overall risk of death (hazard ratio 1.33, p<0.05).
Conclusion: Use of peri-operative β-blockers (metoprolol) in patients with known vascular disease provides both risks and benefits, and these must be considered for each patient individually.
• hyperthyroidism
  • can experience sudden release of thyroid hormone (thyroid storm)
  • treatment: β-blockers and pre-op prophylaxis
• adrenocortical insufficiency (e.g. Addison’s, exogenous steroid use)
  • consider steroid coverage if steroid use of >1 wk in past 6 mo

## Respiratory Diseases

• smoking
  • adverse effects: altered mucus secretion and clearance, decreased small airway caliber and altered immune response
  • abstain at least 8 wk pre-op if possible
  • if unable, abstaining even 24 h pre-op has shown benefit
• asthma
  • increased risk of bronchospasm from intubation, delivery of desflurane
  • pre-op management depends on degree of baseline asthma control
  • pre-op SABA, LABA, ICS, OCS may be used up to 1 wk pre-op to achieve adequate asthma control
  • avoid non-selective β-blockers; cardioselective β-blockers (e.g. metoprolol, atenolol) do not increase risk of bronchospasm in the short term
  • cancel/delay elective surgery for poorly controlled asthma (increased cough or sputum production, active wheezing)
• COPD
  • anesthesia, surgery and analgesia predispose the patient to atelectasis, bronchospasm, pneumonia, prolonged need for mechanical ventilation and respiratory failure
  • cancel/delay elective surgery for acute exacerbation
  • optimize with bronchodilators ± ICS ± antibiotics

## Aspiration

• conditions with increased risk of aspiration:
  • decreased LOC
  • trauma
  • meal within 8 h
  • suspected sphincter incompetence (GERD, hiatus hernia, nasogastric tube)
  • increased abdominal pressure (pregnancy, obesity, bowel obstruction, acute abdomen)
• management: reduce gastric volume and acidity, delay inhibiting airway reflexes, employ rapid sequence induction if increased risk (see Rapid Sequence Induction, A9)
  • increased risk with laryngeal mask instead of endotracheal tube (ETT)

## Monitoring

### Canadian Guidelines to the Practice of Anesthesia and Patient Monitoring

• an anesthetist present: “the only indispensable monitor”
• a completed pre-anesthetic checklist: including ASA class, NPO policy, Hx and investigations
• a peri-operative anesthetic record: HR and BP every 5 min, dose and route of drugs and fluids
• continuous monitoring: see Routine Monitors below

### Routine Monitors for All Cases

• pulse oximeter, apparatus to measure BP, electrocardiography, capnography for general anesthesia and sedation (Ramsey Sedation Scale 4-6), agent-specific anesthetic gas monitor when inhalation anesthetic agents are used
• the following must also be available: temperature probe, peripheral nerve stimulator, stethoscope, appropriate lighting, spirometer

### Elements to Monitor

• anesthetic depth
  • inadequate: blink reflex present when eyelashes lightly touched, HTN, tachycardia, tearing or sweating
  • excessive: hypotension, bradycardia
• oxygenation: pulse oximetry, fraction of inspired O₂ (FiO₂)
• ventilation: verify correct position of ETT, chest excursions, breath sounds, ETCO₂ analysis, end tidal inhaled anesthesia analysis
• circulation: pulse, heart sounds, BP, telemetry, oximetry, CVP, pulmonary capillary wedge pressure
• temperature: temperature probe
Intravenous Agents

- IV induction agents include a selection of non-opioid drugs used to provide amnesia and blunt reflexes
- these are initially used to draw the patient into the maintenance phase of general anesthesia rapidly, smoothly and with little adverse effects
- e.g. propofol, sodium thiopental (not available in North America) or ketamine
- a continuous propofol infusion may also be used for the maintenance phase of GA

Volatile Inhalational Agents

- see Table 15, A26
- general concepts of volatile agents are discussed below
  - e.g. sevoflurane, desflurane, isoflurane, enflurane, halothane and nitrous oxide

MAC (minimum alveolar concentration)

- definition: the alveolar concentration of an agent at one atmosphere (atm) of pressure that will prevent movement in 50% of patients in response to a surgical stimulus (e.g. abdominal incision)
- often 1.2-1.3 times MAC will ablate response to stimuli in the general population
- potency of inhalational agents is compared using MAC
- MAC values are roughly additive when mixing N₂O with another volatile agent (i.e. 0.5 MAC of a potent agent + 0.5 MAC of N₂O = 1 MAC of potent agent; however, this only applies to movement, not other effects such as BP changes and does not hold over the entire N₂O dose range)
- MAC-intubation: the MAC of anesthetic that will inhibit movement and coughing during endotracheal intubation, generally 1.3 MAC
- MAC-block adrenergic response (MAC-BAR): the MAC necessary to blunt the sympathetic response to noxious stimuli, generally 1.5 MAC
- MAC-awake: the MAC of a given volatile anesthetic at which a patient will open their eyes to command, usually 0.3-0.4 of the usual MAC value

Muscle Relaxants and Reversing Agents

- see Tables 16 and 17, A27; Table 18, A28
- depolarizing muscle relaxants: succinylcholine (SCh)
- non-depolarizing muscle relaxants: rocuronium, mivacurium, vecuronium, cistracurium, pancuronium

**Figure 3. Anatomy and physiology of the neuromuscular junction (NMJ)**

**Muscle Relaxants**
- never use without adequate preparation and equipment to maintain airway and ventilation
- muscle relaxation produces the following desired effects:
  1. facilitates intubation
  2. assists with mechanical ventilation
  3. prevents muscle stretch reflex and decreases muscle tone
  4. allows access to the surgical field (intracavitary surgery)
- blocks nicotinic cholinergic receptors in NMJ
- provides skeletal muscle paralysis, including the diaphragm, but spares involuntary muscles such as the heart and smooth muscle
- nerve stimulator is used intraoperatively to assess the degree of nerve block; no twitch response seen with complete neuromuscular blockade

**Reversing Agents for Non-Depolarizing Muscle Relaxants** *(e.g. neostigmine, pyridostigmine, edrophonium)*
- reversal agents are acetylcholinesterase inhibitors
  - inhibits enzymatic degradation of ACh; increases amount of ACh at nicotinic and muscarinic receptors, displacing non-depolarizing muscle relaxant
  - administer reversal agents when there has been some recovery of blockade (i.e. muscle twitch)
- anticholinergic agents (e.g. atropine, glycopyrrolate) are simultaneously administered to minimize muscarinic effect of reversal agents (i.e. bradycardia, salivation and increased bowel peristalsis)

**Airway Anatomy Review**

- normal airway: nares → nasal cavities → nasal pharynx → laryngeal pharynx → trachea
- resistance to airflow through nasal passages accounts for approximately 2/3 of total airway resistance
- pharyngeal airway extends from posterior aspect of the nose to cricoid cartilage
- glottic opening (triangular space formed between the true vocal cords) is the narrowest segment of the laryngeal opening in adults
- when intubating, the glottic opening is used as the space through which one visualizes proper placement of the ETT
- the trachea begins at the level of the thyroid cartilage at the level of C6
- the trachea bifurcates into the right and left main bronchi at the level of T5 (approximately at the sternal angle)

</tbody>
</table>

| **Disadvantages/Contraindications** | | |
| Risk of aspiration if decreased LOC | Risk of gastric aspiration | Insertion can be difficult |
| Cannot ensure airway patency | PPV < 20 cm H2O needed | Muscle relaxant usually needed |
| Inability to deliver precise tidal volume | Oropharyngeal/retropharyngeal pathology or foreign body | Most invasive – see Complications During Laryngoscopy and Intubation, A9 |

| **Other** | | |
| Facilitate airway patency with jaw thrust and chin lift | Does NOT protect against laryngospasm or gastric aspiration | Auscultate to avoid endobronchial intubation |
| Can use oropharyngeal/retropharyngeal airway | Sizing by body weight (approx): | Sizing (approx): |
| 40-50 kg: 3 | Male: 8.0-9.0 mm | Male: 8.0-9.0 mm |
| 50-70 kg: 4 | Female: 7.0-8.0 mm | Female: 7.0-8.0 mm |
| 70-100 kg: 5 | Pediatric: (age/4) + 4 mm | Pediatric: (age/4) + 4 mm |

**Tracheal Intubation**

**Preparing for Intubation**
- failed attempts at intubation can make further attempts more difficult due to tissue trauma
- plan, prepare and assess for potential difficulties (see Pre-Operative Assessment, A2)
- ensure equipment is available and working (e.g. test ETT cuff, check laryngoscope light, machine check)
- pre-oxygenate/denitrogenate: patient breathes 100% O2 for 3-5 min or for 4 vital capacity breaths
- may need to suction mouth and pharynx first

**Proper Positioning for Intubation**
- “sniffing position”: flexion of lower C-spine (C5,6), i.e. bow head forward and extension of upper C-spine at atlanto (C1)-occipital joint, i.e. nose in the air
- contraindicated in known/suspected C-spine fracture/instability
- aligns the three axes of mouth, pharynx and larynx to allow visualization from the oral cavity to the glottis (Figure 5)
- proper position for laryngoscope tip to visualize cords is in the epiglottic vallecula
- contraindicated in known/suspected C-spine fracture/instability

**Tube Insertion**
- ETT insertion can incite a significant sympathetic response due to a “foreign body reflex” in the trachea, including tachycardia, dysrhythmias, myocardial ischemia, increased BP and coughing
- a malpositioned ETT is a potential hazard for the intubated patient
  - if too deep, may result in right endobronchial intubation, which is associated with left-sided atelectasis and right-sided tension pneumothorax
  - if too shallow, may lead to accidental extubation, vocal cord trauma or laryngeal paralysis as a result of pressure injury by the ETT cuff
- the tip of ETT should be located at the midpoint of the trachea at least 2 cm above the carina and the proximal end of the cuff should be placed at least 2 cm below the vocal cords
  - approximately 20-23 cm mark at the right corner of the mouth for men and 19-21 cm for women

**Confirmation of Tracheal Placement of ETT**
- direct
  - visualization of ETT passing through cords
  - bronchoscopic visualization of ETT in trachea
- indirect
  - \( \text{ET}_{\text{CO}_2} \), in exhaled gas measured by capnography
  - auscultate for equal breath sounds bilaterally and absent breath sounds over epigastrium
  - bilateral chest movement, condensation of water vapour in ETT visible during exhalation and no abdominal distention
  - refilling of reservoir bag during exhalation
  - CXR (rarely done): ETT tip at midpoint of thoracic inlet and carina (lateral CXR more sensitive and specific)
- esophageal intubation suspected when
  - \( \text{ET}_{\text{CO}_2} \) zero or near zero on capnograph

**Figure 5. Anatomic considerations in laryngoscopy**
A. Neutral position
B. C-spine flexion
C. C-spine flexion with atlanto-occipital extension
• abnormal sounds during assisted ventilation
• impairment of chest excursion
• hypoxia/cyanosis
• presence of gastric contents in ETT
• distention of stomach/epigastrium with ventilation

### Complications During Laryngoscopy and Intubation
- dental damage
- laceration (lips, gums, tongue, pharynx, esophagus)
- laryngeal trauma
- esophageal or endobronchial intubation
- accidental extubation
- insufficient cuff inflation or cuff laceration: results in leaking and aspiration
- laryngospasm (see *Exubtion*, A17 for definition)
- bronchospasm

### Routine Induction vs. Rapid Sequence Induction (RSI)

- RSI is indicated in patients at risk of regurgitation/aspiration (see *Aspiration*, A5)

#### Table 4. Comparison of Routine Induction vs. RSI

<table>
<thead>
<tr>

</tr>
<tr>
<td>7. Intubation</td>
<td>Intubate, inflate cuff, confirm ET Tposition</td>
<td>Intubate once paralyzed (~45 s after Sch given), inflate cuff, confirm ET Tposition. Cricoid pressure maintained until ET T cuff inflated and placement confirmed</td>
</tr>
</tbody>
</table>

### Difficult Airway

- difficulties with bag-mask ventilation, supraglottic airway, endotracheal intubation, infraglottic airway or surgical airway
- algorithms exist for difficult airways (e.g. *Anesthesiology* 2003;98:3273, *Anaesthesia* 2004;59:675)
- pre-op assessment (history of previous difficult airway, airway examination) and pre-oxygenation are important preventative measures
- if difficult airway expected, consider:
  - awake intubation
  - intubating with bronchoscope, trachlight (lighted stylet), fibre optic laryngoscope, glidescope, etc.
Intraoperative Management

Oxygen Therapy

- in general, the goal of oxygen therapy is to maintain oxygen saturation (\(\text{SaO}_2\)) >90%
- below an \(\text{SaO}_2\) of 90%, a small decrease in saturation corresponds to a large drop in \(\text{PaO}_2\)
- in intubated patients, oxygen is delivered via the ETT
- in patients not intubated, there are many oxygen delivery systems available; the choice depends on oxygen requirements (FiO\(_2\)) and the degree to which precise control of delivery is needed
- cyanosis can be detected at \(\text{SaO}_2\) <85%, frank cyanosis at \(\text{SaO}_2\) = 67%

Low Flow Systems

- acceptable if tidal volume 300-700 mL, respiratory rate (RR) <25, consistent ventilation pattern
- provide O\(_2\) at flows between 0-10 L/min
- dilution of oxygen with room air results in a decrease in FiO\(_2\)
- an increase in minute ventilation (tidal volume x RR) results in a decrease in FiO\(_2\)
- e.g. nasal canula (prong)
  - well tolerated if flow rates <5-6 L/min; drying of nasal mucosa at higher flows
  - nasopharynx acts as an anatomic reservoir that collects O\(_2\)
  - delivered oxygen concentration (FiO\(_2\)) can be estimated by adding 4% for every additional litre of O\(_2\) delivered (e.g. at normal tidal volume and RR, flow rate of 1-6 L/min equates to FiO\(_2\) of 24-44%)

Reservoir Systems

- use a volume reservoir to accumulate oxygen during exhalation thus increasing the amount of oxygen available for the next breath
- simple face mask (Hudson face mask)
  - covers patient's nose and mouth and provides an additional reservoir beyond nasopharynx
  - fed by small bore O\(_2\) tubing at a rate of at least 6 L/min to ensure that exhaled CO\(_2\) is flushed through the exhalation ports and not rebreathed
  - FiO\(_2\) of 55% can be achieved at O\(_2\) flow rates of 10 L/min
- non-rebreather mask
  - reservoir bag and a series of one-way valves direct gas flow from the bag on inhalation and allow release of expired gases on exhalation, thus allowing for oxygen accumulation during intubation
  - O\(_2\) flow rates of 10-15 L/min are needed to maintain the reservoir bag inflation and should deliver FiO\(_2\) >80%

High Flow Systems

- generates flows of up to 50-60 L/min
- meets/exceeds patient's inspiratory flow requirement
- delivers consistent and predictable concentration of O\(_2\)
- Venturi mask
  - delivers specific percentages of oxygen by varying the size of air entrainment
  - port determines the oxygen concentration (i.e. can vary to achieve 24%, 28%, 35%, 50%)
  - enables control of gas humidity
- Puritan mask
  - delivers the highest level of humidified oxygen

Ventilation

- in patients given muscle relaxants, ventilation is maintained with PPV
- if no muscle relaxant is given, patients may have sufficient spontaneous respirations to maintain ventilation or assisted/controlled ventilation can be used
- other indications for mechanical ventilation:
  - apnea
  - hypoventilation
  - intraoperative positioning limiting respiratory excursion (e.g. prone, Trendelenburg)
  - required hyperventilation (to lower ICP)
A11 Anesthesia  Intraoperative Management  Toronto Notes 2014

- deliver positive end expiratory pressure (PEEP)
- increased intrathoracic pressure (e.g. laparoscopic procedure)
- complications of mechanical ventilation:
  - decreased CO₂ due to hyperventilation
  - decreased BP due to decreased venous return from increased intrathoracic pressure
  - alkalemia with over correction of chronic hypercarbia
  - nosocomial pneumonia/bronchitis
- see Respirology, R26 for ventilatory modes

**Causes of Hypocapnea (decreased CO₂)**
- hyperventilation
- hypothermia (decreased metabolic rate)
- decreased pulmonary blood flow (e.g. decreased cardiac output)
- incorrect placement of sampling catheter
- inadequate sampling volume
- V/Q mismatch
  - pulmonary thromboembolism
  - incipient pulmonary edema
  - air embolism

**Causes of Hypercapnea (increased CO₂)**
- hypoventilation
- hyperthermia
- improved pulmonary blood flow after resuscitation or hypotension
- low bicarbonate
- water in capnography device
- anesthetic breathing circuit error
  - inadequate fresh gas flow
  - rebreathing
  - exhausted soda lime
  - faulty circuit absorber valves

**Temperature**

**Causes of Hypothermia (<36.0°C)**
- intraoperative temperature losses are common (e.g. 90% of intraoperative heat loss is transcutaneous), due to:
  - OR environment (cold room, IV fluids, instruments)
  - open wound
- prevent with inflated warming blanket and warmed IV fluids (if giving platelet transfusion, put through a line that does not go through warmer because warmer distorts viability of platelets)

**Causes of Hyperthermia (>37.5-38.3°C)**
- drugs (e.g. atropine)
- blood transfusion reaction
- infection/sepsis
- medical disorder (e.g. thyrotoxicosis)
- malignant hyperthermia (see Uncommon Complications, A24)
- over-zealous warming efforts

**Heart Rate**

**Cardiac Arrest**
- pulseless arrest occurs due to 4 cardiac rhythms divided into shockable and non-schockable rhythms
  - shockable: ventricular fibrillation (VF) and ventricular tachycardia (VT)
  - non-shockable: asystole and pulseless electrical activity (PEA)
- for VF/VT, key to survival is good early CPR and defibrillation
- for asystole/PEA, key to survival is good early CPR and exclude all reversible causes
- reversible causes of PEA arrest (5 Hs and 5 Ts):
  - 5 Hs: hypothermia, hypovolemia, hypoxia, hydrogen ions (acidosis), hypo/hyperkalemia
  - 5 Ts: tamponade (cardiac), thrombosis (pulmonary), thrombosis (coronary), tension pneumothorax, toxins (overdose/poisoning)
- for management of cardiac arrest, see ACLS Guidelines (Figure 13), A28

**Intraoperative Tachycardia**
- tachycardia = HR >150 bpm; divided into narrow complex supraventricular tachycardias (SVT) or wide complex tachycardias
- SVT: sinus tachycardia, atrial fibrillation/flutter, accessory pathway mediated tachycardia, paroxysmal atrial tachycardia
- wide complex tachycardia: VT, SVT with aberrant conduction

---

**Causes of Intraoperative Hypoxia**
- **Inadequate oxygen supply**: e.g. breathing system disconnection, obstructed or malpositioned ETT, leaks in the anesthetic machine, loss of oxygen supply.
- **Hyperventilation**
  - Ventilation-perfusion inequalities: e.g. atelectasis, pneumonia, pulmonary edema, pneumothorax.
- **Reduction in oxygen carrying capacity**: e.g. anemia, carbon monoxide poisoning, methemoglobinemia, hemoglobinopathy.
- **Leftward shift of the hemoglobin-oxygen saturation curve**: e.g. hypothermia, decreased 2,3-DPG, alkalosis, hypocarbia, carbon monoxide poisoning.
- **Right-to-left cardiac shunt**

**Hypothermia (32°-35.9°C)**
- Impact on Outcomes
  - Increased risk of wound infections due to impaired immune function.
  - Increases the period of hospitalization by delaying healing.
  - Reduces platelet function and impairs activation of coagulation cascade increasing blood loss and transfusion requirements.
  - Triples the incidence of VT and morbid cardiac events.
  - Decreases the metabolism of anesthetic agents prolonging post-op recovery.
• causes of sinus tachycardia:
  - shock/hypovolemia/blood loss
  - anxiety/pain/light anesthesia
  - full bladder
  - anemia
  - febrile illness/sepsis
  - drugs (e.g. atropine, cocaine, dopamine, epinephrine, ephedrine, isoflurane, isoproterenol, pancuronium)
  - Addisonian crisis, hypoglycemia, transfusion reaction, malignant hyperthermia
  - for management of tachycardia, see ACLS Guidelines (Figure 14), A29

**Intraoperative Bradycardia**
• bradycardia = HR <50 bpm; most concerning are 2nd degree (Type 2 Mobitz) and 3rd degree heart block, which can both degenerate into asystole
• causes of sinus bradycardia:
  - increased parasympathetic tone vs. decreased sympathetic tone
  - must rule out hypoxemia
  - arrhythmias (see Cardiology and Cardiovascular Surgery, C12)
  - baroreceptor reflex due to increased ICP or increased BP
  - vagal reflex (oculocardiac reflex, carotid sinus reflex, airway manipulation)
  - drugs (e.g. Sch, opioids, edrophonium, neostigmine, halothane, digoxin, β-blockers)
  - high spinal/epidural anesthesia
  - for management of bradycardia, see ACLS Guidelines (Figure 15), A29

**Blood Pressure**

**Causes of Intraoperative Hypotension/Shock** (sBP <90 mmHg or MAP <60 mmHg)
  a) hypovolemic/hemorrhagic shock
    - most common form of shock, due to blood loss or dehydration

</table>

b) obstructive shock
  - obstruction of blood into or out of the heart
  - increased JVP, distended neck veins, increased systemic vascular resistance, insufficient cardiac output (CO)
  - e.g. tension pneumothorax, cardiac tamponade, pulmonary embolism

c) cardiogenic shock
  - myocardial dysfunction
  - increased JVP, distended neck veins, increased systemic vascular resistance, decreased CO
  - e.g. dysrhythmias, ischemia/infarct, cardiomyopathy, acute valvular dysfunction

d) septic shock
  - see Infectious Diseases, ID22
  - bacterial, viral, fungal, endotoxins/mediators cause vasodilation and capillary leakage
  - associated with contamination of open wounds, intestinal injury or penetrating trauma
  - fever, decreased JVP, wide pulse pressure, increased CO, increased HR, decreased systemic vascular resistance ± pressors
  - initial treatment: antibiotics, volume expansion
e) spinal/neurogenic shock
  - decreased sympathetic tone
  - hypotension without tachycardia or peripheral vasoconstriction (warm skin)
f) anaphylactic shock
  - see Emergency Medicine, ER30
  - acute/subacute generalized allergic reaction due to an inappropriate or excessive immune response (type I hypersensitivity)
treatment of anaphylactic shock:
- moderate reaction: generalized urticaria, angioedema, wheezing, tachycardia
  - epinephrine (1:1000) 0.3-0.5 mg SC
  - antihistamines: diphenhydramine (Benadryl®) 25-50 mg IM
  - salbutamol (Ventolin®) 1 cc via nebulizer
- severe reaction/evolution: severe wheezing, laryngeal/pulmonary edema, shock
  - ABCs, may need ETT due to airway edema
  - epinephrine (1:1000) 0.1-0.3 mg IV (or via ETT if no IV access) to start, repeat as needed
  - antihistamines: diphenhydramine (Benadryl®) 50 mg IV (~1 mg/kg)
  - steroids: hydrocortisone (Solucortef®) 100 mg IV (~1.5 mg/kg) or methylprednisolone (Solumedrol®) 1 mg/kg IV q6h x 24 h
  - large volumes of crystalloid may be required

g) drugs
- vasodilators, high spinal anesthetic interfering with sympathetic outflow
h) other
- transfusion reaction, Addisonian crisis, thyrotoxicosis, hypothyroid, aortocaval syndrome
  - see Hematology, H52 and Endocrinology, E35, E22, E26

Causes of Intraoperative Hypertension
- inadequate anesthesia causing pain and anxiety
- pre-existing HTN, coarctation or preeclampsia
- hypoxemia/hypercarbia
- hypervolemia
- drugs (e.g. ephedrine, epinephrine, cocaine, phenylephrine, ketamine)
- allergic/anaphylactic reaction
- hypermetabolic states: malignant hyperthermia, neuroleptic malignant syndrome
  - see Psychiatry, PS43, thyroid storm, pheochromocytoma (see Endocrinology, E25, E36)

Fluid Balance and Resuscitation
- total requirement = maintenance + deficit + ongoing loss
- in surgical settings this formula must take into account multiple factors including pre-operative fasting/decreased fluid intake, increased losses during or before surgery, fluid shifting during surgery, fluids given with blood products and medications

What is the Maintenance?
- average healthy adult requires approximately 2500 mL water/d
  - 200 mL/d GI losses
  - 800 mL/d insensible losses (respiration, perspiration)
  - 1500 mL/d urine (beware of renal failure)
- increased requirements with fever, sweating, GI losses (vomiting, diarrhea, NG suction), adrenal insufficiency, hyperventilation and polyuric renal disease
- decreased requirements with anuria/oliguria, SIADH, highly humidified atmospheres and CHF
- 4:2:1 rule to calculate maintenance requirements (applies to crystalloids only)
  - 4 mL/kg/h first 10 kg
  - 2 mL/kg/h second 10 kg
  - 1 mL/kg/h for remaining weight >20 kg
- maintenance electrolytes
  - Na+: 3 mEq/kg/d
  - K+: 1 mEq/kg/d
- e.g. 50 kg patient maintenance requirements
  - fluid = 40 + 20 + 30 = 90 mL/h = 2160 mL/d = 2.16 L/d
  - Na⁺ = 150 mEq/d (therefore 150 mEq / 2.16 L/d = 69 mEq/L)
  - K⁺ = 50 mEq/d (therefore 50 mEq / 2.16 L/d = 23 mEq/L)
- above patient's requirements roughly met with 2/3 D5W, 1/3 NS
  - e.g. 2/3 + 1/3 at 100 mL/h with 20 mEq KCl per litre

What is the Deficit?
- patients should be adequately hydrated prior to anesthesia
- total body water (TBW) = 60% or 50% of total body weight for an adult male or female, respectively (e.g. for a 70 kg adult male TBW = 70 x 0.6 = 42 L)
- total Na⁺ content determines ECF volume; [Na⁺] determines ICF volume
- hypovolemia due to volume contraction
  - extra-renal Na⁺ loss
    - GI: vomiting, NG suction, drainage, fistulae, diarrhea
    - skin/resp: insensible losses (fever), sweating, burns
    - vascular: hemorrhage
renal Na+ and H2O loss
- diuretics
- osmotic diuresis
- hypoaldosteronism
- salt-wasting nephropathies
renal H2O loss
- diabetes insipidus (central or nephrogenic)
hypovolemia with normal or expanded ECF volume
- decreased CO
- redistribution
  - hypoalbuminemia: cirrhosis, nephrotic syndrome
  - capillary leakage: acute pancreatitis, rhabdomyolysis, ischemic bowel, sepsis, anaphylaxis

- replace water and electrolytes as determined by patient’s needs
- with chronic hyponatremia, correction must be done gradually over >48 h to avoid central pontine myelinolysis

### Table 6. Signs and Symptoms of Dehydration

<table>
<thead>

<td>Oliguria, orthostatic hypotension, tachycardia, low volume pulse, cool extremities, reduced filling of peripheral veins and CVP, hemoconcentration, apathy</td>
</tr>
<tr>
<td>9%</td>
<td>Severe</td>
<td>Profound oliguria or anuria and compromised CNS function with or without altered sensorium</td>
</tr>
</tbody>
</table>

### What are the Ongoing Losses?
- tubes
  - Foley catheter, NG, surgical drains
- third spacing (other than ECF, ICF)
  - pleura, GI, retroperitoneal, peritoneal
  - evaporation via exposed viscera, burns
- blood loss
- ongoing loss due to surgical exposure and evaporative losses

### IV Fluids
- replacement fluids include crystalloid and colloid solutions
- IV fluids improve perfusion but NOT O2 carrying capacity of blood

#### Crystalloid Infusion
- salt-containing solutions that distribute within ECF
- maintain euvoelma in patient with blood loss: 3 mL crystalloid infusion per 1 mL of blood loss for volume replacement (i.e. 3:1 replacement). Controversy surrounds this as an initial vs. maximal replacement target
- if large volumes are to be given, use balanced fluids such as Ringer’s lactate or PlasmaLyte®, as too much normal saline (NS) may lead to hyperchloremic metabolic acidosis

#### Colloid Infusion (see Blood Products, A15)
- includes protein colloids (albumin and gelatin solutions) and non-protein colloids (starches, e.g. hydroxyethyl starch (HES) and dextrans)
- distributes within intravascular volume
- 1:1 ratio (infusion:blood loss) only in terms of replacing intravascular volume
- HES colloids remain in intravascular space (metabolized by plasma serum amylase and renally excreted); two available in Canada: Voluven® and Pentaspan®
- beware of coagulopathy with large volume colloid infusions

### Table 7. Colloid HES Solutions

### Blood Products

- see Hematology, H50

#### Red Blood Cells (RBCs)
- 1 U RBCs = approx. 300 mL
- 1 U RBCs increases Hb by 10 g/L in a 70 kg patient
- RBCs may be diluted with colloid/crystalloid to decrease viscosity
- decision to transfuse based on initial blood volume, premorbid Hb level, present volume status, expected further blood loss, patient health status, patient consent
- massive transfusion = >1 x blood volume/24 h

#### Autologous RBCs
- replacement of blood volume with one’s own RBCs
- may decrease complications (infectious, febrile, etc.)
- alternative to homologous transfusion in elective procedures, but only if adequate Hb and no infection
- pre-op phlebotomy prior to elective surgery (up to 3U collected 3-5 wk before surgery)
- intraoperative salvage and filtration (cell saver); contraindicated in contaminated (e.g. bowel, abscess) or cancer cases

#### Non-RBC Products
- fresh frozen plasma (FFP)
  - contains all plasma clotting factors and fibrinogen close to normal plasma levels
  - to prevent/treat bleeding due to coagulation factor depletion/deficiencies, liver impairment
- cryoprecipitate
  - contains Factors VIII and XIII, von Willebrand Factor (vWF), fibrinogen
- platelets
  - used in thrombocytopenia, massive transfusions, impaired platelet function
- albumin
  - selective intravascular volume expander
- erythropoietin
  - can be used pre-operatively to stimulate erythropoiesis

#### Complications Due to Transfusion
- infectious risks: HIV, hepatitis B/C, Epstein-Barr virus (EBV), cytomegalovirus (CMV), brucellosis, malaria, salmonellosis, measles, syphilis
- hypervolemia
- electrolyte changes: increased K⁺ in stored blood
- dilutional coagulopathy
- dilutional thrombocytopenia
- hypothermia
- citrate toxicity
- hypocalcemia
- iron overload
- transfusion-related immunosuppression: peri-operative transfusion may be associated with increased risk of post-operative infection, increased short-term mortality and possible cancer recurrence
- see Hematology, H52 for list of transfusion reactions

#### Calculating Acceptable Blood Losses (ABL)
- Blood volume
  - term infant  80 mL/kg
  - adult male  70 mL/kg
  - adult female  60 mL/kg
- Calculate estimated blood volume (EBV) (e.g. in a 70 kg male, approx. 70 mL/kg)
  \[
  \text{EBV} = 70 \text{ kg} \times 70 \text{ mL/kg} = 4800 \text{ mL}
  \]
- Decide on a transfusion trigger, i.e. the Hb level at which you would begin transfusion, (e.g. 70 g/L for a person with Hb(i) = 150 g/L)
  \[
  \text{Hb(f)} = 70 \text{ g/L}
  \]
- Calculate
  \[
  \text{ABL} = \text{Hct(i)} - \text{Hct(f)} \times \frac{\text{EBV}}{\text{Hct(i)}}
  \]
  \[
  = \frac{150 - 70}{150} \times 4800
  = 2613 \text{ mL}
  \]
- Therefore in order to keep the Hb level above 70 g/L, RBCs would have to be given after approximately 2.6 L of blood has been lost.
Table 9. Immune Transfusion Reactions

<table>
<thead>
<tr>
<th>Reaction</th>
<th>Risk</th>
<th>Cause</th>
<th>Presentation</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-Hemolytic: Febrile</td>

Transfusion and risk of infection in Canada: Update 2012. Paediatr Child Health 2012;17:e102-e111

A Multicenter, Randomized, Controlled Clinical Trial of Transfusion Requirements in Critical Care

In 1999, 340:409-417

Purpose: To determine whether a restrictive strategy of RBC transfusion and a liberal strategy produce equivalent results in critically ill patients.

Study: Randomized controlled trial with 60 d follow-up.

Patients: 838 critically ill patients with evidence of acute hypovolemia after initial transfusion who had Hb concentrations of <80 g/L within 72 h after admission to the ICU. Median age 57.5 yr, 62.5% male.

Intervention: Patients were randomly assigned to either a restrictive strategy of transfusion, in which RBCs were transfused if the Hb dropped <100 g/L, and Hb concentrations were maintained between 70-90 g/L, or a liberal strategy, in which transfusions were given when the Hb dropped <100 g/L and Hb concentrations were maintained between 100-120 g/L.

Main Outcomes: All cause mortality rates at 30 d and 60 d, mortality rates during the stay in ICU and hospitalization, survival times during the first 30 d and rates of organ failure and dysfunction.

Results: Overall, 30 d mortality was similar in the two groups. However, the rates were significantly lower with the restrictive transfusion strategy among patients who were less acutely ill (8.7% vs. 16.1%) and who were less than 55 yr of age (5.7% vs. 13%), but not among patients with clinically significant cardiac disease.

The mortality rate during hospitalization was significantly lower in the restrictive strategy group (22.2% vs. 28.1%).

Conclusions: With the possible exception of patients with acute MI and unstable angina, a restrictive strategy of RBC transfusion is as effective as, and possibly superior to, a liberal transfusion strategy in critically ill patients.
Extubation

- performed by trained, experienced personnel because reintubation may be required
- criteria:
  - patient must no longer have intubation requirements (see Table 3, Tracheal Intubation, A8)
  - patency: airway must be patent
  - protection: airway reflexes intact
  - patient must be oxygenating and ventilating spontaneously
- laryngospasm more likely in semiconscious patient; must ensure adequate LOC
- general guidelines:
  - ensure patient has normal neuromuscular function (peripheral nerve stimulator monitoring) and hemodynamic status
  - ensure patient is breathing spontaneously with adequate rate and tidal volume
  - suction secretions from pharynx
  - deflate cuff, remove ETT on inspiration (vocal cords abducted)

Complications of Extubation

- early extubation
  - aspiration
  - laryngospasm
- late extubation
  - transient vocal cord incompetence
  - edema (glottic, subglottic)
  - pharyngitis, tracheitis

Laryngospasm

- defined as forceful involuntary spasm of laryngeal muscles caused by stimulation of superior laryngeal nerve (e.g. by oropharyngeal secretions, blood, extubation)
- causes partial or total airway obstruction
- prevention: extubate while patient is still deeply under anesthesia or fully awake
- treatment: bag-mask ventilation with 100% oxygen, low-dose propofol (0.5-1.0 mg/kg) optional, low-dose succinylcholine (0.25-1 mg/kg) and reintubation if hypoxia develops

Post-Operative Care

- pain management should be continuous from OR to post-anesthetic care unit (PACU) to hospital ward and home
- pain service may assist with management of post-operative inpatients

Post-Operative Nausea and Vomiting (PONV)

- hypotension and bradycardia must be ruled out
- pain and surgical manipulation also cause nausea
- often treated with dimenhydrinate (Gravol®), metoclopramide (Maxeran®) (not with bowel obstruction), prochlorperazine (Stemetil®), ondansetron (Zofran®), granisetron (Kytril®)

Post-Operative Confusion and Agitation

- ABCs first – confusion or agitation can be caused by airway obstruction, hypercapnea, hypoxemia
- neurologic status (Glasgow Coma Scale, pupils), residual paralysis from anesthetic
- pain, distended bowel/bladder
- fear/anxiety/separation from caregivers, language barriers
- metabolic disturbance (hypoglycemia, hypercalcemia, hyponatremia – especially post-TURP)
- intracranial cause (stroke, raised intracranial pressure)
- drug effect (ketamine, anticholinergics)
- elderly patients are more susceptible to post-operative delirium

Risk Factors for Post-Operative Nausea and Vomiting (PONV)

- Young age
- Female
- History of PONV
- Non-smoker
- Type of surgery: ophtho, ENT, abdo/pelvic, plastics
- Type of anesthetic: N2O, opioids, volatile agents

Drugs for Preventing Post-Operative Nausea and Vomiting

Cochrane Database Syst Rev 2006;3:CD004125
Purpose: To evaluate the efficacy of antiemetics in preventing PONV.
Methods: A meta-analysis was performed looking at randomized controlled trials comparing an antiemetic to either a second antiemetic or placebo. Trials looking at dosing and/or timing of medication administration were also included. PONV was used as the primary outcome.
Results: 727 studies involving 103,237 patients. Eight drugs significantly reduced the occurrence of PONV, namely: droperidol, metoclopramide, ondansetron, tropisetron, dolasetron, dexamethasone, cyclizine and granisetron. Relative risk (RR) versus placebo varied between 0.60 and 0.80. Side effects included a significant increase in drowsiness for droperidol (RR 1.32) and headache for ondansetron (RR 1.16). The cumulative number needed to treat was 3.57.
Conclusion: Antiemetic medication is effective for reducing the occurrence of PONV. However, further investigation needs to be done to determine whether antiemetics can cause more severe (and likely rare) side effects, which could alter how liberally they are used.
Pain Management

Definitions
- nociception: detection, transduction and transmission of noxious stimuli
- pain: perception of nociception which occurs in the brain

Acute Pain
- pain of short duration (<6 wk) usually associated with surgery, trauma or acute illness; often associated with inflammation
- usually limited to the area of damage/trauma and resolves with healing

Pharmacological Management of Acute Pain
- ask the patient to rate the pain out of 10, or use visual analog scale, to determine severity
-

</table>

Opioid Equivalency
- 10 mg morphine
- 100 mg codeine
- 5 mg oxycodone
- 2 mg hydromorphone

Figure 8. WHO analgesia ladder

Use NSAIDs with Caution in Patients with:
- Asthma
- Coagulopathy
- GI ulcers
- Renal insufficiency
- Pregnancy, 3rd trimester

Common Side Effects of Opioids
- Nausea and vomiting
- Constipation
- Sedation
- Pruritus
- Abdominal pain
- Urinary retention
- Respiratory depression

When prescribing opioids, consider:
- Breakthrough dose
- Anti-emetics
- Laxative

PCA Parameters
- Loading dose
- Bolus dose
- Lockout interval
- Continuous infusion (optional)
- Maximum 4 h dose (limit)

Advantages of PCA
- Improved patient satisfaction
- Fewer side effects
- Accommodates patient variability
- Accommodates changes in opioid requirements

Figure 9. Acute pain mechanism

Figure 9. Acute pain mechanism

Pharmacological Management of Acute Pain
- ask the patient to rate the pain out of 10, or use visual analog scale, to determine severity

PCA Parameters
- Loading dose
- Bolus dose
- Lockout interval
- Continuous infusion (optional)
- Maximum 4 h dose (limit)

Advantages of PCA
- Improved patient satisfaction
- Fewer side effects
- Accommodates patient variability
- Accommodates changes in opioid requirements
• patient controlled analgesia (PCA)
  • involves the use of computerized pumps that can deliver a constant infusion as well as bolus breakthrough doses of parenterally-administered opioid analgesics
  • limited by lockout intervals
  • most commonly used agents: morphine and hydromorphone
  • refer to Table 14, A26 for suggested infusion rate, PCA dose and lockout intervals

Opioid Antagonists (naloxone, naltrexone)
• opioid overdose manifests primarily at CNS (e.g. respiratory depression) – manage ABCs
• opioid antagonists competitively inhibit opioid receptors, predominantly µ receptors
• naloxone is short-acting (t1/2 = 1 h); effects of narcotic may return when naloxone wears off; therefore, the patient must be observed closely following its administration
• naltrexone is longer-acting (t1/2 = 10 h); less likely to see return of opioid effects
• relative overdose of naloxone may cause nausea, agitation, sweating, tachycardia, hypertension, re-emergence of pain, pulmonary edema, seizures (essentially opioid withdrawal)

Neuropathic Pain
• pain caused by peripheral or central nervous system injury, often described as burning, lancinating, shooting, or tingling
• results in allodynia (pain in response to normally painless stimuli) or hyperalgesia (increased sensitivity to painful stimuli)
• consider adding anticonvulsants (gabapentin, pregabalin) or low-dose tricyclic antidepressant as opioids are ineffective

Chronic Pain
• pain of duration or intensity that persists beyond normal tissue healing and adversely affects functioning
• may have nociceptive and neuropathic components; dysregulation of analgesic pathways implicated
• in the peri-operative period, consider continuing regular long-acting analgesics, and augmenting with regional techniques, adjuvants, additional opioid analgesia, and non-pharmacological techniques

Regional Anesthesia

Definition of Regional Anesthesia
• local anesthetic agent (LA) applied around a peripheral nerve at any point along the length of the nerve (from spinal cord up to, but not including, the nerve endings) for the purpose of reducing or preventing impulse transmission
• no CNS depression (unless overdose of local anesthetic); patient remains conscious
• regional anesthetic techniques categorized as follows:
  ▪ epidural and spinal anesthesia (neuraxial anesthesia)
  ▪ peripheral nerve blocks
  ▪ IV regional anesthesia (e.g. Bier block)

Preparation for Regional Anesthesia

Patient Preparation
• thorough pre-operative evaluation and assessment of patient
• technique explained to patient
• sedation may be indicated before block
• monitoring should be as extensive as for general anesthesia

Relative Indications for Regional Anesthesia
• avoids some of the dangers of general anesthesia (e.g. known difficult intubation, severe respiratory failure, etc.)
• patient specifically requests regional anesthesia
• high quality post-operative pain relief
• general anesthesia not available/contraindicated
• titration of LA dosage for differential blockade (e.g. can block pain but preserve motor function)

Complications of Regional Anesthesia
• failure of technique/inadequate anesthesia
• unintentional total spinal anesthesia
• systemic drug toxicity due to overdose or intravascular injection (leading to CNS and CVS complications)
• injury to nerve root/spinal cord (nerve deficit), to epidural vein (hematoma), to peripheral nerve (intraneural injection)
• infection (e.g. osteitis, epidural abscess, meningitis)
• spinal and epidural: sympathetic blockade causing hypotension and bradycardia (occurs early, followed by sensory then motor blockade)
• post-dural puncture headache

Benefits of Regional Anesthesia
• Reduced peri-op pulmonary complications
• Reduced peri-op analgesia requirements
• Decreased POIV
• Reduced peri-op blood loss
• Ability to monitor CNS status during procedure
• Improved perfusion
• Lower incidence of VTE

Patient Controlled Opioid Analgesia versus Conventional Opioid Analgesia for Postoperative Pain
Cochrane DB Syst Rev 2006;4:CD003348

Purpose: To evaluate the efficacy of patient controlled analgesia (PCA) as compared to conventional ‘as-needed’ analgesia administration providing pain relief in post-operative patients.

Methods: Meta-analyses of randomized controlled trials comparing PCA vs. conventional administration of opioid analgesia. Assessment employed a visual analog scale (VAS) for pain intensity along with overall analgesic consumption, patient satisfaction, length of stay and adverse side effects.

Results: 55 studies with a total of 2023 patients receiving PCA and 1638 patients with standard as-needed opioid administration. PCA provided significantly better pain control through 72 h post-operatively, but patients consumed significantly more opioids (>7 mg morphine/24 h, P < 0.05).

Significantly more patients reported pruritus in the PCA group compared to control with a number needed to harm of 13. No significant difference in overall length of stay in hospital, sedation level, nausea/vomiting or urinary retention.

Conclusions: PCA is more effective than standard as-needed administration for reducing post-operative pain. However, patients using PCA consume more opioids overall and have more pruritus.

To ronto Notes 2014
Epidural and Spinal Anesthesia

Anatomy of Spinal/Epidural Area
- spinal cord extends to L2, dural sac to S2 in adults
- nerve roots (cauda equina) from L2 to S2
- needle inserted below L2 should not encounter cord, thus L3-L4, L4-L5 interspace commonly used
- structures penetrated
  - skin
  - subcutaneous fat
  - supraspinous ligament
  - interspinous ligament
  - ligamentum flavum (last layer before epidural space)
  - dura + arachnoid for spinal anesthesia

Table 11. Epidural versus Spinal Anesthesia

<table>
<thead>
<tr>
<th></th>
<th>Epidural</th>
<th>Spinal</th>

</tbody>
</table>

Contraindications to Spinal/Epidural Anesthesia
- absolute contraindications
  - lack of proper equipment or trained personnel
  - lack of IV access
  - allergy to LA
  - infection at puncture site or underlying tissues
  - coagulopathies/anti-coagulation
  - raised ICP
  - sepsis/bacteremia
  - hemodynamic instability/uncorrected hypovolemia

Landmarking Epidural/Spinal Anesthesia
- Spinal processes should be maximally flexed
- L4 spinous processes found between iliac crests
- Common sites of insertion are L3-L4 and L4-L5

Figure 10. Landmarks for placement of epidural/spinal

Classic Presentation of Dural Puncture Headache
- Onset 6 h-3 d after dural puncture
- Postural component (worse sitting)
- Occipital or frontal localization
- ± tinnitus, diplopia
• relative contraindications
  ▪ pre-existing neurological disease
  ▪ aortic/mitral valve stenosis (i.e. fixed cardiac output states)
  ▪ previous spinal surgery, severe kyphoscoliosis
  ▪ severe/unstable psychiatric disease or emotional instability

**Peripheral Nerve Blocks**

• utilizes ultrasound guidance and electrical stimulation (needle will stimulate target nerve/plexus), may be used to guide deposition of local anesthetic around nerve while avoiding neural trauma or intraneural injection
• approximately 2-4 per 10,000 risk of late neurologic injury
• most major nerves or nerve plexi can be targeted (e.g. brachial plexus block, femoral nerve block, sciatic nerve block, etc.)

**Contraindications to Peripheral Nerve Blockade**

• allergy to LA
• patient refusal, lack of cooperation
• lack of resuscitation equipment
• lack of IV access
• certain types of pre-existing neurological dysfunction (e.g. ALS, MS, diabetic neuropathy)
• local infection at block site
• bleeding disorder

**Local Anesthesia**

**Local Anesthetic Agents (LA)**

• see Table 19 for list of LA agents, A28

**Definition and Mode of Action**

• LA are drugs that block the generation and propagation of impulses in excitable tissues: nerves, skeletal muscle, cardiac muscle, brain
• LA bind to receptors on the cytosolic side of the Na⁺ channel, inhibiting Na⁺ flux and thus blocking impulse conduction
• different types of nerve fibres undergo blockade at different rates

**Absorption, Distribution, Metabolism**

• LA readily crosses the blood-brain barrier (BBB) once absorbed into the bloodstream
• ester-type LA (procaine, tetracaine) are broken down by plasma and hepatic esterases; metabolites excreted via kidneys
• amide-type LA (lidocaine, bupivacaine) are broken down by hepatic mixed-function oxidases (P450 system); metabolites excreted via kidneys

**Selection of LA**

• choice of LA depends on
  ▪ onset of action: influenced by pKa (the lower the pKa, the higher the concentration of the base form of the LA and the faster the onset of action)
  ▪ duration of desired effects: influenced by protein binding (longer duration of action when protein binding of LA is strong)
  ▪ potency: influenced by lipid solubility (agents with high lipid solubility penetrate the nerve membrane more easily)
  ▪ unique needs (e.g. sensory blockade with relative preservation of motor function by bupivacaine at low doses)
  ▪ potential for toxicity

**Systemic Toxicity**

• see Table 19, A28 for maximum doses, potency and duration of action for common LA agents
• occurs by accidental intravascular injection, LA overdose, or unexpectedly rapid absorption
• CNS effects first appear to be excitatory due to initial block of inhibitory fibres; then subsequent block of excitatory fibres
• CNS effects (in order of appearance)
  ▪ numbness of tongue, perioral tingling, metallic taste
  ▪ disorientation, drowsiness
  ▪ tinnitus

![Figure 11. Local anesthetic systemic toxicity](image-url)
• visual disturbances
• muscle twitching, tremors
• unconsciousness
• convulsions, seizures
• generalized CNS depression, coma, respiratory arrest

• CVS effects
  • vasodilation, hypotension
  • decreased myocardial contractility
  • dose-dependent delay in cardiac impulse transmission
    * prolonged PR, QRS intervals
    * sinus bradycardia
  • CVS collapse

• treatment of systemic toxicity
  • early recognition of signs, get help
  • 100% O₂, manage ABCs
  • diazepam or sodium thiopental may be used to increase seizure threshold
  • manage arrhythmias (see ACLS Guidelines, A28)
  • Intralipid® 20% to bind local anesthetic in circulation

### Local Infiltration and Hematoma Blocks

#### Local Infiltration
- injection of tissue with LA, producing a lack of sensation in the infiltrated area due to LA acting on nerve endings
- suitable for small incisions, suturing, excising small lesions
- can use fairly large volumes of dilute LA to infiltrate a large area
- low concentrations of epinephrine (1:100,000-1:200,000) cause vasoconstriction, thus reducing bleeding and prolonging the effects of LA by reducing systemic absorption

#### Fracture Hematoma Block
- special type of local infiltration for pain control during manipulation of certain fractures
- hematoma created by fracture is infiltrated with LA to anesthetize surrounding tissues
- sensory blockade may only be partial
- no muscle relaxation

### Topical Anesthetics
- various preparations of local anesthetics available for topical use, may be a mixture of agents, e.g. EMLA cream is a combination of 2.5% lidocaine and prilocaine
- must be able to penetrate the skin or mucous membrane

### Obstetrical Anesthesia

#### Physiologic Changes in Pregnancy
- **airway**
  - possible difficult airway as tissues becomes edematous and friable especially in labour
- **respiratory**
  - decreased FRC and increased O₂ consumption → desaturation occurs more quickly during apnea
- **cardiovascular system**
  - increased blood volume > increased RBC mass → mild anemia
  - decreased SVR proportionately greater than increased CO → decreased BP
  - prone to decreased BP due to aortocaval compression – therefore for surgery, a pregnant patient is positioned in left uterine displacement using a wedge under her right flank
- **central nervous system**
  - decreased MAC due to hormonal effects
  - increased block height due to engorged epidural veins
- **gastrointestinal system**
  - delayed gastric emptying
  - increased volume and acidity of gastric fluid
  - decreased LES tone
  - increased abdominal pressure
  - combined, these lead to an increased risk of aspiration – therefore for surgery, a pregnant patient is given sodium citrate 30 cc PO immediately before surgery to neutralize gastric acidity

#### Where Not to Use LA with Epinephrine
“Ears, Fingers, Toes, Penis, Nose”

#### The Effect of Epidural Analgesia on Labour, Maternal, and Neonatal Outcomes: A Systematic Review

**Am J Obstet Gynecol** 2002;186:S69-77

**Study:** Meta-analysis of 14 studies with 4324 women.

**Selection Criteria:** RCTs and prospective cohort studies between 1980-2001 comparing epidural analgesia to parenteral opioid administration during labour.

**Types of Participants:** Healthy women with uneventful pregnancies.

**Intervention:** Participants were randomized to either epidural analgesia or parenteral opioid administration during labour.

**Outcomes and Results:**
- **Maternal**
  - there were no differences between the 2 groups in first-stage labour length, incidence of Caesarean delivery, incidence of instrumented vaginal delivery for dystocia, nausea, or mid-to-low back pain post-partum. However, second-stage labour length was longer (mean=15 min) and there were greater reports of fever and hypotension in the epidural group. Also, lower pain scores and greater satisfaction with analgesia were reported among the epidural group. There was no difference in lactation success at 6 wk and urinary incontinence was more frequent in the epidural group immediately post-partum, but not at 3 mo or 1 yr (evidence from PC studies only). Neonates – there were no differences between the 2 groups for incidence of fetal heart rate abnormalities, intrapartum meconium, poor 5-min Apgar score, or low umbilical artery pH. However, the incidence of poor 1-min Apgar scores and need for neonatal naloxone were higher in the parenteral opioid group.
- **Conclusions:** Epidural analgesia is a safe intrapartum method for labour pain relief and women should not avoid epidural analgesia for fear of neonatal harm, Caesarean delivery, breastfeeding difficulties, long-term back pain or long-term urinary incontinence.
Options for Analgesia during Labour
- psychoprophylaxis – Lamaze method
- patterns of breathing and focused attention on fixed object
- systemic medication
  - easy to administer, but risk of maternal or neonatal depression
  - opioids most commonly used if delivery is not expected within 4 h
- inhalational analgesia
  - easy to administer, makes uterine contractions more tolerable, but does not relieve pain completely
  - 50% nitrous oxide
- neuraxial analgesia
  - provides excellent analgesia with minimal depressant effects
  - hypotension is the most common complication
  - maternal BP monitored q2-5 min for 15-20 min after initiation and regularly thereafter
  - epidural usually given as it preferentially blocks sensation, leaving motor function intact

Options for Caesarean Section
- neuraxial: spinal or epidural
- general: used if contraindications or time precludes regional blockade

Pediatric Anesthesia

Respiratory System
- in comparison to adults, anatomical differences in infants include
  - large head, short trachea/neck, large tongue, adenoids and tonsils
  - narrow nasal passages (obligate nasal breathers until 5 mo)
  - narrowest part of airway at the level of the cricoid vs. glottis in adults
  - epiglottis is longer, U shaped and angled at 45 degrees; carina is wider and is at the level of T2 (T4 in adults)
- physiologic differences include
  - faster RR, immature respiratory centres which are depressed by hypoxia/hypercapnea (airway closure occurs in the neonate at the end of expiration)
  - less oxygen reserve during apnea – decreased total lung volume, vital and functional reserve capacity together with higher metabolic needs
  - greater V/Q mismatch – lower lung compliance due to immature alveoli (mature at 8 yr)
  - greater work of breathing – greater chest wall compliance, weaker intercostals/diaphragm and higher resistance to airflow

Cardiovascular System
- blood volume at birth is approximately 80 mL/kg; transfusion should be started if >10% of blood volume lost
- children have a high HR and low BP
- CO is dependent on HR, not stroke volume because of low heart wall compliance; therefore, bradycardia → severe compromise in CO

Temperature Regulation
- vulnerable to hypothermia
- minimize heat loss by use of warming blankets, covering the infant's head, humidification of inspired gases and warming of infused solutions

Central Nervous System
- MAC of halothane is increased compared to the adult (i.e. 0.75% adult, 0.87% neonates, 1.2% infant)
- NMJ is immature for the first 4 wk of life and thus there is an increased sensitivity to non-depolarizing relaxants
- parasympathetics mature at birth, sympathectics mature at 4-6 mo → autonomic imbalance
- infant brain is 12% of body weight and receives 34% of CO (adult: 2% body weight and 14% CO)

Glucose Maintenance
- infants less than 1 yr old can become seriously hypoglycemic during pre-operative fasting and post-operatively if feeding is not recommenced as soon as possible
- after 1 yr, children are able to maintain normal glucose homeostasis in excess of 8 h

Pharmacology
- higher dose requirements because of higher TBW (75% vs. 60% in adults) and greater volume of distribution
- barbiturates/opioids more potent due to greater permeability of BBB

Nociceptive Pathways in Labour and Delivery
Labour
- Cervical dilation and effacement stimulates visceral nerve fibres entering the spinal cord at T10-L1

Delivery
- Distention of lower vagina and perineum causes somatic nociceptive impulses via the pudendal nerve entering the spinal cord at S2-S4

To increase alveolar minute ventilation in neonates, increase respiratory rate, not tidal volume.

Neonate: 30-40 breaths/min
Age 1-13: \( 24 - \frac{\text{age}}{2} \) breaths/min

To calculate diameter (mm) of tracheal tube in children after 1 year:

Ages 1-3 years: \( \text{age} + 4 \)
Ages 4-8 years: \( \text{age} + 6 \)
Ages 9-12 years: \( \text{age} + 8 \)
Ages 13-15 years: \( \text{age} + 10 \)

Length (cm) of tracheal tube:

Ages 0-4 years: \( \frac{\text{age}}{2} + 12 \)
Ages 5-9 years: \( \frac{\text{age}}{2} + 15 \)
Ages 10-15 years: \( \frac{\text{age}}{2} + 18 \)
• muscle relaxants
  ▪ non-depolarizing
    ▪ immature NMJ, variable response
  ▪ depolarizing
    ▪ must pre-treat with atropine or may experience profound bradycardia and/or sinus node arrest due to PNS > SNS (also dries oral secretions)
    ▪ more susceptible to arrhythmias, hyperkalemia, rhabdomyolysis, myoglobinemia, masseter spasm and malignant hyperthermia

Uncommon Complications

Malignant Hyperthermia (MH)

• hypermetabolic disorder of skeletal muscle
• due to an uncontrolled increase in intracellular Ca\(^{2+}\) (because of an anomaly of the ryanodine receptor which regulates the Ca\(^{2+}\) channel in the sarcoplasmic reticulum of skeletal muscle)
• autosomal dominant inheritance
• incidence of 1-5 in 100,000, may be associated with skeletal muscle abnormalities such as dystrophy or myopathy
• anesthetic drugs triggering MH include
  ▪ all inhalational agents except nitrous oxide
  ▪ depolarizing muscle relaxants: SCh

Clinical Picture

• onset: immediate or hours after contact with trigger agent
  ▪ increased oxygen consumption
  ▪ increased ET\(_{CO_2}\) on capnograph
  ▪ tachycardia/dysrhythmia
  ▪ tachypnea/cyanosis
  ▪ diaphoresis
  ▪ hypertension
  ▪ increased temperature (late sign)
• muscular symptoms
  ▪ trismus (masseter spasm) common but not specific for MH (occurs in 1% of children given SCh with halothane anesthesia)
  ▪ tender, swollen muscles due to rhabdomyolysis
  ▪ trunk or total body rigidity

Complications

• coma
• DIC
• rhabdomyolysis
• myoglobinuric renal failure/hepatic dysfunction
• electrolyte abnormalities (e.g. hyperkalemia) and secondary arrhythmias
• ARDS
• pulmonary edema
• can be fatal if untreated

Prevention

• suspect MH in patients with a family history of problems/death with anesthetic
• avoid all trigger medications (use regional if possible) and use vapour free equipment
• central body temp and ET\(_{CO_2}\) monitoring

Malignant Hyperthermia Management [Based on Malignant Hyperthermia Association of the U.S. (MHAUS) Guidelines, 2008]

1. notify surgeon, discontinue volatile agents and succinylcholine, hyperventilate with 100% oxygen at flows of 10 L/min or more; halt the procedure as soon as possible
2. dantrolene 2.5 mg/kg IV, through large-bore IV if possible
  ▪ repeat until there is control of signs of MH; sometimes up to 30 mg/kg is necessary
3. bicarbonate 1-2 mEq/kg if blood gas values are not available for metabolic acidosis
4. cool patients with core temperature >39°C
  ▪ lavage open body cavities, stomach, bladder, rectum; apply ice to surface; infuse cold saline IV
  ▪ stop cooling if temperature is <38°C to prevent drift to <36°C
5. dysrhythmias usually respond to treatment of acidosis and hyperkalemia
  ▪ use standard drug therapy except Ca\(^{2+}\) channel blockers as they may cause hyperkalemia and cardiac arrest in presence of dantrolene
6. hyperkalemia
   - treat with hyperventilation, bicarbonate, glucose/insulin, calcium
   - bicarbonate 1-2 mEq/kg IV, calcium chloride 10 mg/kg or calcium gluconate 10-50 mg/kg
   for life-threatening hyperkalemia and check glucose levels hourly

7. follow ET, electrolytes, blood gases, creatine kinase (CK), core temperature, urine output/colour with Foley-catheter, coagulation studies
   - if CK and/or potassium rises persistently or urine output falls to <0.5 mL/kg/h, induce diuresis to >1 mL/kg/h urine to avoid myoglobinuric renal failure
8. maintain anesthesia with benzodiazepines, opioids and propofol
9. transfer to ICU bed

### Abnormal Pseudocholinesterase

- pseudocholinesterase hydrolyzes SCh and mivacurium
- 1 in 50 people will be heterozygous for an abnormal pseudocholinesterase allele
- heterozygotes will experience a prolonged duration of muscular blockade (2-3x normal)
- homozygotes will have a greatly increased duration of blockade (4-8 h) following administration of SCh
- SCh and mivacurium are contraindicated in those with abnormal pseudocholinesterase
- if SCh or mivacurium are given accidentally, treat with mechanical ventilation until function returns to normal (do not use cholinesterase inhibitors)

### Common Medications

| CNS                | Increased ICP | Increased ICP | Decreased cerebral metabolic rate | Increased ICP | ECG seizure-like activity | Increased ICP | Increased cerebral blood flow | — |
| Resp               | Respiratory depression (severely decreased TV, increased RRI), decreased response to respiratory CO₂ reflexes, bronchodilation | — |
| CVS                | Less decrease of contractility, stable HR | Tachycardia with rapid increase in concentration | Decreased BP and CO, increased HR, theoretical chance of coronary steal** | Stable HR, decreased contractility | Decreased BP, CO, HR and conduction sensitizes myocardium to epinephrine-induced arrhythmias | Can cause decreased HR in pediatric cases in those with existing heart disease |
| MSK                | Muscle relaxation, potentiation of other muscle relaxants, uterine relaxation | — |

*Properties and Adverse Effects of N₂O

Due to its high MAC, nitrous oxide is combined with other anesthetic gases to attain surgical anesthesia. A MAC of 104% is possible in a pressurized chamber only.

Second Gas Effect: see Determinants of Speed of Onset of Volatile Anesthetics sidebar, A6

Expansion of closed spaces: closed spaces such as a pneumothorax, the middle ear, bowel lumen and ETT cuff will markedly enlarge if N₂O is administered.

Diffusion hypoxia: during anesthesia, the washout of N₂O from body stores into alveoli can dilute the alveolar O₂, creating a hypoxic mixture if the original O₂ is low.

**Coronary steal: isoflurane causes small vessel dilation which may compromise blood flow to areas of the heart with fixed perfusion [e.g. stents, atherosclerosis].
### Table 16. Depolarizing Muscle Relaxants (Non-Competitive): Succinylcholine (SCh)

<table>
<thead>
<tr>
<th>Mechanism of Action</th>
<th>Mimics ACh and binds to ACh receptors causing prolonged depolarization; initial fasciculation may be seen, followed by temporary paralysis secondary to blocked ACh receptors by SCh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intubating Dose</td>
<td>1-1.5 mg/kg</td>
</tr>
<tr>
<td>Onset</td>
<td>30-60 s – RAPID (fastest of all muscle relaxants)</td>
</tr>
<tr>
<td>Duration</td>
<td>3-5 min – SHORT (no reversing agent for SCh)</td>
</tr>
<tr>
<td>Metabolism</td>
<td>SCh is hydrolyzed by plasma cholinesterase (pseudocholinesterase), found only in plasma and not at the NMJ</td>
</tr>
<tr>
<td>Indications</td>
<td>• Assist intubation</td>
</tr>
<tr>
<td></td>
<td>• Increased risk of aspiration (need rapid paralysis and airway control)</td>
</tr>
<tr>
<td></td>
<td>• Short procedures (e.g. full stomach), hiatus hernia, obesity, pregnancy, trauma</td>
</tr>
<tr>
<td></td>
<td>• Electroconvulsive therapy (ECT)</td>
</tr>
<tr>
<td></td>
<td>• Laryngospasm</td>
</tr>
<tr>
<td>Side Effects</td>
<td>1. SCh also stimulates muscarinic cholinergic autonomic receptors (in addition to nicotinic receptors)</td>
</tr>
<tr>
<td></td>
<td>• May cause bradycardia, dysrhythmias, sinus arrest, increased secretions of salivary glands (especially in children)</td>
</tr>
<tr>
<td></td>
<td>2. Hyperkalemia</td>
</tr>
<tr>
<td></td>
<td>• Disruption of motor nerve activity causes proliferation of extrajunctional (outside NMJ) cholinergic receptors</td>
</tr>
<tr>
<td></td>
<td>• Depolarization of an increased number of receptors by SCh may lead to massive release of potassium out of muscle cells</td>
</tr>
<tr>
<td></td>
<td>• Patients at risk:</td>
</tr>
<tr>
<td></td>
<td>• 3rd degree burns 24 h-6 mo after injury</td>
</tr>
<tr>
<td></td>
<td>• Traumatic paralysis or neuromuscular diseases (e.g. muscular dystrophy)</td>
</tr>
<tr>

Basic Anatomy Review

Coronary Circulation

- conventional arterial supply to the heart arises from the right and left coronary arteries, which originate from the root of the aorta (see Figure 1)
  - right coronary artery (RCA)
    - acute marginal branches
    - atrioventricular (AV) nodal artery
    - posterior interventricular artery (PIV) = posterior descending artery (PD)
  - left main coronary artery (LCA): two major branches
    - left anterior descending artery (LAD)
      - septal branches
      - diagonal branches
    - left circumflex artery (LC)
      - obtuse marginal branches
  - dominance of circulation
    - right-dominant circulation: PIV and at least one posterolateral branch arise from RCA (80%)
    - left-dominant circulation: PIV and at least one posterolateral branch arise from LC (15%)
    - balanced circulation: dual supply of posteroinferior LV from RCA and LC (5%)
  - the sinoatrial (SA) node is supplied by the SA nodal artery, which may arise from the RCA (60%) or LCA (40%)
  - most venous blood from the heart drains into the RA through the coronary sinus, although a small amount drains through the Thebesian veins into all four chambers, contributing to the physiologic R-L shunt

![Figure 1. Anatomy of the coronary arteries (right anterior oblique projection)](image-url)
Cardiac Anatomy

- layers of the heart
  - endocardium
  - myocardium
  - epicardium
  - visceral pericardium
  - pericardial cavity
  - parietal pericardium

- valves
  - semilunar valves: no subvalvular apparatus present
    - aortic valve, 3 valve leaflets: separates LV and ascending aorta
    - pulmonic valve, 3 valve leaflets: separates RV and main pulmonary artery (PA)
  - atrioventricular valves: subvalvular apparatus present in the form of chordae tendinae and papillary muscles
    - tricuspid valve, 3 valve leaflets: separates RA and RV
    - mitral valve, 2 valve leaflets: separates LA and LV

- conduction system (see Figure 3)
  - SA node governs pacemaking control
  - anterior-, middle- and posterior-internal nodal tracts carry impulses in the right atrium and along Bachmann's bundle in the left atrium
  - atrial impulses converge at the AV node
    - the AV node is the only conducting tract from the atria to the ventricles because of electrical isolation by the annulus fibrosis (except when accessory pathways are present)
    - the bundle of His bifurcates into left and right bundle branches (LBB and RBB)
    - LBB further splits into anterior and posterior fascicles
    - RBB and fascicles of LBB give off Purkinje fibres which conduct impulses into the ventricular myocardium
cardiovascular innervation
• sympathetic nerves
  • innervate the SA node, AV node, ventricular myocardium and vasculature
  • SA node (β1) fibres increase pacemaking activity (chronotropy)
  • cardiac muscle (β1) fibres increase contractility (inotropy) to help increase cardiac output
  • stimulation of β1- and β2-receptors in the skeletal and coronary circulation causes vasodilatation
• parasympathetic nerves
  • innervate the SA node, AV node, atrial myocardium but few vascular beds
  • basal vagal tone dominates the tonic sympathetic stimulation of the SA node and AV node resulting in slowing of pacemaker activity and conduction (i.e. reduced dromotropy – if only affecting AV node conduction)
  • parasympathetics have very little impact on total peripheral vascular resistance

Differential Diagnoses of Common Presentations

Note: bold text indicates most common, underlined text indicates life threatening

Chest Pain
• cardiac
  • MI/angina
  • myocarditis
  • pericarditis/Dressler’s syndrome
  • cardiac tamponade
• pulmonary
  • pneumonia
  • pulmonary embolism (PE)
  • pneumothorax/hemorthorax
    • tension pneumothorax
  • empyema
  • pulmonary neoplasm
  • bronchiectasis
  • TB
• gastrointestinal
  • esophageal: spasm, GERD, esophagitis, ulceration, achalasia, neoplasm, Mallory-Weiss syndrome, esophageal rupture
  • gastrointestinal
    • PUD
    • gastritis
    • pancreatitis
    • biliary colic
    • mediastinal
      • lymphoma
      • thymoma
    • vascular
      • dissecting aortic aneurysm
      • aortic rupture
    • surface structures
      • costochondritis
      • rib fracture
      • skin (bruising, herpes zoster)
      • breast
      • anxiety/psychosomatic

Loss of Consciousness
• hypovolemia
• cardiac
  • structural or obstructive causes
    • acute coronary syndrome
    • aortic stenosis
    • hypertrophic cardiomyopathy (HCM)
  • cardiac tamponade, constrictive pericarditis
  • arrhythmias (see Arrhythmias, C12)
• respiratory
  • massive pulmonary embolism
  • pulmonary hypertension
  • hypoxia
  • hypercapnia
• neurologic
  • stroke/TIA (esp. vertebrobasilar insufficiency)
  • migraine
  • seizure
  • metabolic
    • anemia
    • hypoglycemia
  • drugs
    • antihypertensives
    • antiarrhythmics
    • diuretics
  • vasovagal
    • autonomic dysfunction
    • diabetic neuropathy
    • psychiatric
    • panic attack

Local Edema
• inflammation/infection
• venous or lymphatic obstruction
  • thrombophlebitis/deep vein thrombosis
• venous insufficiency
• chronic lymphangitis
• lymphatic tumour infiltration
• filariasis
• increased hydrostatic pressure/fluid overload
  • heart failure
  • pregnancy
  • drugs (e.g. CCBs)
  •iatrogenic(e.g. IV fluids)
• decreased oncotic pressure/hypoalbuminemia
• nephrotic syndrome
• liver cirrhosis
• malnutrition
• increased capillary permeability
  • severe sepsis
• hormonal
• hypothyroidism
• exogenous steroids
• pregnancy
• estrogens
Palpitations

- cardiac
  - arrhythmias (PAC, PVC, SVT, VT)
  - valvular heart disease
  - hypertrophic cardiomyopathy (HCM)
- endocrine
  - thyrotoxicosis
  - pheochromocytoma
  - hypoglycemia
- systemic
  - fever
  - anemia
- drugs
  - stimulants and anticholinergics
  - psychiatric
  - panic attack

Dyspnea

- cardiovascular
  - acute MI
  - CHF/LV failure
  - aortic/mitral stenosis
  - aortic/mitral regurgitation
  - arrhythmia
  - cardiac tamponade
  - constrictive pericarditis
  - left-sided obstructive lesions (e.g. left atrial myxoma)
  - elevated pulmonary venous pressure
- respiratory
  - airway disease
    - asthma
    - COPD exacerbation
    - upper airway obstruction (anaphylaxis, foreign body, mucus plugging)
  - parenchymal lung disease
    - ARDS
- non-cardiovascular
  - pneumonia
  - interstitial lung disease
  - pulmonary vascular disease
  - pulmonary embolism
  - pulmonary HTN
  - pulmonary vasculitis
  - pleural disease
    - pneumothorax
    - pleural effusion
  - neurovascular and chest wall disorders
    - C-spine injury
    - polymyositis, myasthenia gravis, Guillain-Barré syndrome
    - kyphoscoliosis
    - anxiety/psychosomatic
    - hematological/metabolic
    - anemia, acidosis, hypercapnia

Cardiac Diagnostic Tests

Electrocardiography (ECG) Basics

- the electrocardiogram (ECG) is a graphic representation of the electrical activity of the heart recorded from the surface of the body
- on the ECG graph
  - the horizontal axis represents time
    - 1 mm (1 small square) = 40 msec
    - 5 mm (1 large square) = 200 msec (at paper speed 25 mm/s)
  - the vertical axis represents voltage
    - 1 mm (1 small square) = 0.1 mV
    - 10 mm (2 large squares) = 1 mV (at standard gain setting)
- leads
  - standard 12-lead ECG
    - limb leads: I, II, III, aVL, aVR, aVF
    - precordial leads: V1-V6 (V1-V2 septal, V3-V4 anterior, V5-V6 lateral)
  - additional leads
    - right-sided leads: V3R-V6R (useful in RV infarction and dextrocardia)
    - lateral = I, aVL, V5, V6; inferior = II, III, aVF; anterior = V1-V4

Approach to ECGs

RATE

- normal = 60-100 bpm (atrial rate: 150-250 bpm = paroxysmal tachycardia, 250-350 bpm = atrial flutter, >350 bpm = AFib)
- regular rhythm
  - to calculate the rate, divide 300 by number of large squares between 2 QRS complexes (there are 300 large squares in 1 min: 300 x 200 msec = 60 s)
  - or remember 300-150-100-75-60-50-43 (rate falls in this sequence with the number of large squares between 2 QRS complexes)
- irregular rhythm
  - rate = 6 x number of R-R intervals in 10 s (the “rhythm strips” are 10 s recordings)
  - types: wandering pacemaker, multifocal atrial tachycardia, AFib
  - atrial escape = 60-80 bpm; junctional escape = 40-60 bpm; ventricular escape = 20-40 bpm

For more examples and practice visit www.ecgmadesimple.com.
RHYTHM

- regular: R-R interval is the same across the tracing
- irregular: R-R interval varies across the tracing
- regularly-irregular: repeating pattern of varying R-R intervals
- irregularly irregular: R-R intervals vary erratically
- normal sinus rhythm (NSR)
  - P wave precedes each QRS; QRS follows each P wave
  - P wave axis is normal (positive in leads I, aVF)
  - rate between 60-100 bpm

AXIS

- mean axis indicates the direction of the mean vector
- can be determined for any waveform (P, QRS, T)
- the standard ECG reported QRS axis usually refers to the mean axis of the anterior plane; it indicates the mean direction of ventricular depolarization forces
- QRS axis in the frontal plane (see Figure 7)
  - normal axis: -30º to 90º (i.e. positive QRS in leads I and II)
  - left axis deviation (LAD): axis < -30º
  - right axis deviation (RAD): axis > 90º
- QRS axis in the horizontal plane is not routinely calculated; it is directed posteriorly and to the left
  - transition from negative to positive is usually in lead V3

INTRAVENTRICULAR CONDUCTION ABNORMALITIES

Left Bundle Branch Block (LBBB)

- Complete LBBB
  - QRS duration > 120 msec
  - Broad notched or slurred R waves in leads I, aVL and usually V5 and V6
  - Deep broad S waves in leads V1-2
  - Secondary ST-T changes (–ve in leads with broad R waves, +ve in V1-2) are usually present
  - LBBB can mask ECG signs of MI

Right Bundle Branch Block (RBBB)

- Complete RBBB
  - QRS duration > 120 msec
  - Positive QRS in lead V1 (VSR’ or occasionally broad R wave)
  - Broad S waves in leads I, V5-6 (> 40 msec)
  - Usually secondary T wave inversion in leads V1-2

Left Anterior Fascicular Block (LAFB)

- Left axis deviation (-30º to -90º)
  - Small q and prominent R in leads I and aVL
  - Small r and prominent S in leads II, III, and aVF

Left Posterior Fascicular Block (LPFB)

- Right axis deviation (110º to 180º)
  - Small r and prominent S in leads I and aVL
  - Small q and prominent R in leads II, III, and aVF

Bifascicular Block

- Left axis deviation (-30º to -90º)
  - Small q and prominent R
  - The first 60 msec (1.5 small squares) of the QRS shows the pattern of LAFB or LPFB
  - Bifascicular block refers to impaired conduction in two of the three fascicles, most commonly a RBBB and left anterior hemiblock; the appearance on an ECG meets the criteria for both types of blocks

Nonspecific Intraventricular Block

- QRS duration > 120 msec
- absence of criteria for LBBB or RBBB

Figure 7. Axial reference system
Each lead contains a (+) area displayed by the bold arrows. Impulses traveling toward the positive region of the lead results in an upward deflection in that lead. Normal QRS axis is between -30º and +90º.

Figure 8. Complete LBBB, RBBB, LVH and RVH (please see online examples for the full range of waveforms and the text for additional characteristics)
HYPERTROPHY AND CHAMBER ENLARGEMENT

Left Ventricular Hypertrophy (LVH)  
- S in V1 + R in V5 or V6 > 35 mm above age 40, (>40 mm for age 31-40, >45 mm for age 21-30)  
- R in aVL > 11 mm  
- R in I + S in III > 25 mm  
- Additional criteria:  
  - LV strain pattern (ST depression and T wave inversion in leads I, aVL, V4-V6)  
  - Left atrial enlargement  

Right Ventricular Hypertrophy (RVH)  
- Right axis deviation  
- R/S ratio > 1 or QR in lead V1  
- RV strain pattern: ST segment depression and T wave inversion in leads V1-2

Left Atrial Enlargement (LAE)  
- Biphasic P wave with the negative terminal component of the P wave in lead V1 ≥ 1 mm wide and ≥ 1 mm deep  
- P wave > 120 msec, notched in lead II (“P mitrale”)  

Right Atrial Enlargement (RAE)  
- P wave > 2.5 mm in height in leads II, III, or aVF (“P pulmonale”)  

ISCHEMIA/INFARCTION  
- look for the anatomic distribution of the following ECG abnormalities (see Table 1)  
- ischemia  
  - ST segment depression  
  - T wave inversion (most commonly in V1-V6)  
- injury  
  - transmural (involving the epicardium): ST elevation in the leads facing the area injured/infarced; transient ST elevation may occur in patients with coronary artery spasm (e.g. Prinzmetal angina) which can be slight or prominent (>10 mm)  
  - subendocardial: marked ST depression in the leads facing the affected area; may be accompanied by enzyme changes and other signs of MI, may also occur with angina

- evolving infarction (ST elevation in contiguous leads = acute MI)  
- “typical” sequential changes of evolving MI  
  1. hyperacute T waves (tall, symmetric T waves) in the leads facing the infarcted area, with or without ST elevation  
  2. ST elevation (injury pattern) in the leads facing the infarcted area  
    - usually in the first hours post infarct  
    - in acute posterior infarction, there is ST depression in V1-V3 (reciprocal to ST elevation in the posterior leads, that are not recorded in the standard 12-lead ECG)  
  3. significant Q waves: >40 msec or >1/3 of the total QRS (hours to days post-infarct)  
- this classical sequence does not always occur  
- Q waves of infarction may appear in the very early stages, with or without ST changes  
- non-Q wave infarction: there may be only ST or T changes despite clinical evidence of infarction  
- completed infarction  
- abnormal Q waves (wide Q waves may be found in III and aVL in normal individuals)  
  - duration >40 msec (>30 msec in aVF for inferior infarction)  
  - Q/QRS voltage ratio is >33%  
- abnormal R waves (R/S ratio > 1, duration >40 msec) in V1 and more frequently in V2 are found in posterior infarction (usually in association with signs of inferior and/or lateral infarction)  

Figure 10. Typical ECG changes with infarction  
- evolving infarction (ST elevation in contiguous leads = acute MI)  
- “typical” sequential changes of evolving MI  
- significant Q waves: >40 msec or >1/3 of the total QRS (hours to days post-infarct)  
- completed infarction  
- abnormal Q waves (wide Q waves may be found in III and aVL in normal individuals)  
- duration >40 msec (>30 msec in aVF for inferior infarction)  
- Q/QRS voltage ratio is >33%  
- abnormal R waves (R/S ratio > 1, duration >40 msec) in V1 and more frequently in V2 are found in posterior infarction (usually in association with signs of inferior and/or lateral infarction)  

ISCHEMIA/INFARCTION  
- look for the anatomic distribution of the following ECG abnormalities (see Table 1)  
- ischemia  
  - ST segment depression  
  - T wave inversion (most commonly in V1-V6)  
- injury  
  - transmural (involving the epicardium): ST elevation in the leads facing the area injured/infarced; transient ST elevation may occur in patients with coronary artery spasm (e.g. Prinzmetal angina) which can be slight or prominent (>10 mm)  
  - subendocardial: marked ST depression in the leads facing the affected area; may be accompanied by enzyme changes and other signs of MI, may also occur with angina

- evolving infarction (ST elevation in contiguous leads = acute MI)  
- “typical” sequential changes of evolving MI  
  1. hyperacute T waves (tall, symmetric T waves) in the leads facing the infarcted area, with or without ST elevation  
  2. ST elevation (injury pattern) in the leads facing the infarcted area  
    - usually in the first hours post infarct  
    - in acute posterior infarction, there is ST depression in V1-V3 (reciprocal to ST elevation in the posterior leads, that are not recorded in the standard 12-lead ECG)  
  3. significant Q waves: >40 msec or >1/3 of the total QRS (hours to days post-infarct)  
- this classical sequence does not always occur  
- Q waves of infarction may appear in the very early stages, with or without ST changes  
- non-Q wave infarction: there may be only ST or T changes despite clinical evidence of infarction  
- completed infarction  
- abnormal Q waves (wide Q waves may be found in III and aVL in normal individuals)  
  - duration >40 msec (>30 msec in aVF for inferior infarction)  
  - Q/QRS voltage ratio is >33%  
- abnormal R waves (R/S ratio > 1, duration >40 msec) in V1 and more frequently in V2 are found in posterior infarction (usually in association with signs of inferior and/or lateral infarction)  

Figure 9. LAE, RAE (please see online examples and text above for characteristics)

Significant Q wave  
- Septal depolarization by the left bundle  
- Seen in leads I, II, III, aVL, V5, V6  
- < 40 msec

Insignificant Q wave  
- Septal depolarization by the left bundle  
- Seen in leads I, II, III, aVL, V5, V6  
- < 40 msec

Differential of ST Segment Changes  
ST Elevation “I HELP A PAL”  
- Ischemia with reciprocal changes  
- Hypothermia (Osborne waves)  
- Early repolarization (normal variant; need old ECGs)  
- LBBB  
- Post-MI  
- Acute STEMI  
- Prinzmetal’s (Vasospastic) angina  
- Acute pericarditis (diffuse changes)  
- Left/right ventricular aneurysm

ST Depression “WAR SHIP”  
- WPW syndrome  
- Acute NSTEMI  
- RBBB/LBBB  
- STEMI with reciprocal changes  
- Hypertrophy (LVH or RVH) with strain  
- Ischemia  
- Post-MI

MISCELLANEOUS ECG CHANGES

Electrolyte Disturbances
- hyperkalemia (see Figure 11)
  - mild to moderate (K⁺ 5-7 mmol/L): tall peaked T waves
  - severe (K⁺ >7 mmol/L): progressive changes whereby P waves flatten and disappear, QRS widens and may show bizarre patterns, axis shifts left or right, ST shift with tall T waves
- hypokalemia (see Figure 12)
  - ST segment depression, prolonged QT interval, low T waves, prominent U waves (U>T)
  - enhances the toxic effects of digitalis
- hypercalcemia: shortened QT interval
- hypocalcemia: prolonged QT interval

Hypothermia
- sinus bradycardia
- when severe, prolonged QRS and QT intervals
- AFib with slow ventricular response and other atrial/ventricular dysrhythmias
- Osborne J waves (see Figure 13): "hump-like" waves at the junction of the J point and the ST segment

Pericarditis
- early: diffuse ST segment elevation ± PR segment depression, upright T waves
- later: isoelectric ST segment, flat or inverted T waves
- low voltage if chronic constrictive pericarditis
- tachycardia

Drug Effects
- digitalis
  - therapeutic levels may be associated with "digitalis effect" (see Figure 14):
    - ST downsloping or "scooping"
    - T wave depression or inversion
    - QT shortening ± U waves
    - slowing of ventricular rate in AFib
  - toxic levels associated with:
    - arrhythmias: paroxysmal atrial tachycardia (PAT) with conduction block, severe bradyarhythmia in AFib, accelerated junctional rhythms, PVCs, ventricular tachycardia (see Arrhythmias, C12)
    - "regularization" of ventricular rate in AFib due to a junctional rhythm and AV dissociation
  - amiodarone, quinidine, phenothiazines, tricyclic antidepressants, antipsychotics, some antihistamines, some antibiotics: prolonged QT interval, U waves

Figure 11. Hyperkalemia

Figure 12. Hypokalemia

Figure 13. Osborne J waves of a hypothermic patient

Low Voltage
- Definition: total QRS height in precordial leads <10 mm and limb leads <5 mm

Differential diagnosis
- Myocardial disease
  - Ischemia
  - Cardiomyopathy (usually infiltrative type), myocarditis
- Pericardial effusion
- Thick chest wall/barrel chest: COPD, obesity
- Generalized edema
- Hypothyroidism/myxedema
- Inappropriate voltage standardization

High Voltage
- Definition: total QRS height in precordial leads >17 mm and limb leads >11 mm

Differential diagnosis
- Myocardial disease
  - Hypertrophy
  - Valvular disease
  - Pericarditis

Digitalis Side Effects
- Palpitations, fatigue, visual changes (yellow vision), decreased appetite, hallucinations, confusion and depression.

Quinidine
- Wide P wave
- Wide QRS
- Prolonged QT
- ± ST depression
- ± U wave
Pulmonary Disorders
- cor pulmonale (often secondary to COPD)
  - low voltage, RAD, poor R wave progression
  - RAE and RVH with strain
  - multifocal atrial tachycardia (MAT)
- massive PE
  - sinus tachycardia and AFib/atrial flutter are the most common arrhythmias
  - RAD, RVH with strain – most specific sign is S1Q3T3 (S in I, Q and inverted T wave in III)

Cardiac Biomarkers
- provide diagnostic and prognostic information in acute coronary syndromes and in heart failure

<table>
<thead>
<tr>
<th>Enzyme</th>
<th>Peak Duration Elevated</th>
<th>DDX of Elevation</th>

</tr>
<tr>
<td>CK-MB</td>
<td>1 d, 3 d</td>
<td>MI, myocarditis, pericarditis, muscular dystrophy, cardiac defibrillation, etc.</td>
</tr>
</tbody>
</table>

- check troponin I at presentation and 8 h later ± creatine kinase-MB (CK-MB; depends on local laboratory protocol)
- new CK-MB elevation can be used to diagnose reinfarction
- other biomarkers of cardiac disease:
  - AST and LDH also increased in MI (low specificity)
  - BNP and NT-proBNP: secreted by ventricles in response to increased end-diastolic pressure and volume
    - DDx of elevated BNP: CHF, AFib, PE, COPD exacerbation, pulmonary HTN

Ambulatory ECG
- indications for outpatient testing: palpitations, syncope, antiarrhythmic drug monitoring, arrhythmia surveillance in patients with documented or potentially abnormal rhythms, and surveillance of non-sustained arrhythmias that can lead to prophylactic intervention
- available technologies
  - Holter monitor
    - battery operated, continually records up to 3 leads for 24-48 h
    - symptoms recorded by patient on Holter clock for correlation with ECG findings
  - continuous loop recorder (diagnostic yield 66-83%)
    - worn continuously and can record data before and after patient activation for symptomatic episodes (usually worn for 2 wk)
  - external and implantable devices
    - external devices can be transtelephonically downloaded
  - implantable loop recorder (ILR): cannot be transtelephonically downloaded; left in place for 14 to 18 mo

Echocardiography

Transthoracic Echocardiography (TTE)
- ultrasound beams are directed across the chest wall to obtain images of the heart
- indications: evaluation of left ventricular ejection fraction (LVEF), wall motion abnormalities, myocardial ischemia and complications of MI, chamber size, wall thickness, valve morphology, proximal great vessel morphology, pericardial effusion, unexplained hypotension, murmurs, syncope, congenital heart disease
- use with Doppler to quantify degree of valvular stenosis or regurgitation
Transoesophageal Echocardiography (TEE)
- ultrasound probe inserted into the esophagus to allow for better resolution of the heart and structures
- better visualization of posterior structures, including left atrium, mitral and aortic valves, interatrial septum
- invasive procedure used to complement transthoracic echocardiography
- indications: intracardiac thrombi, tumours, valvular vegetations (infective endocarditis), aortic dissection, aortic atheromas, prosthetic valve function, shunt, technically inadequate transthoracic study
- use with Doppler to quantify degree of valvular stenosis or regurgitation

Stress Echocardiography
- echocardiography in combination with either physiologic (exercise treadmill or bike testing) or pharmacologic (dobutamine infusion) stress
- validated in demonstrating myocardial ischemia and assessing viability
- provides information on the global left ventricular response to exercise
- used for valvular heart disease evaluation

Contrast Echocardiography
- contrast agents injected into the bloodstream to improve imaging of the heart
- conventional agent: agitated saline (contains microbubbles of air)
- allows visualization of right heart and intracardiac shunts, most commonly patent foramen ovale (PFO) and sometimes intrapulmonary shunt
- newer contrast agents are capable of crossing the pulmonary bed and achieving left heart opacification following intravenous injection; these contrast agents improve visualization of endocardial borders and enhance evaluation of LV ejection fraction, wall motion abnormalities, and intracardiac mass

Stress Testing

EXERCISE TESTING
- cardiovascular stress test that uses treadmill or bicycle exercise with electrocardiographic and blood pressure monitoring
- guidelines for use:
  - patients with intermediate (10-90%) pretest probability of CAD based on age, gender and symptoms
  - exercise test results stratify patients into risk groups:
    - low risk patients can be treated medically without invasive testing
    - intermediate risk patients may need additional testing in the form of exercise imaging studies or cardiac catheterization
    - high risk patients should be referred for cardiac catheterization

Indications for Terminating Exercise Stress Test
- drop in systolic blood pressure of >10 mmHg from baseline despite an increase in workload, when accompanied by other evidence of ischemia
- moderate to severe angina
- ST elevation (>1 mm) in leads without diagnostic Q-waves (other than V1 or aVR)
- increasing nervous system symptoms (e.g. ataxia, dizziness, or near syncope)
- signs of poor perfusion (cyanosis or pallor)
- technical difficulties in monitoring ECG or systolic blood pressure
- patient’s desire to stop
- sustained ventricular tachycardia

Interpretation
- the most commonly used ECG criteria for a positive exercise test: ≥1 mm of horizontal or downsloping ST-segment depression or elevation (at least 60 to 80 msec after the end of the QRS complex)
- ST depression <1 mm at rest, no left bundle branch block, no digoxin or estrogen use

NUCLEAR CARDIOLOGY
- myocardial perfusion imaging (MPI) with ECG-gated single photon emission computed tomography (SPECT), using radiolabelled tracer
- evaluates myocardial viability, detects ischemia, and assesses perfusion and LV function simultaneously
- predicts the likelihood of further cardiac event rates independent of the patient’s history, examination, resting ECG, and stress ECG
- often denoted as MIBI scan with reference to radiolabelled tracer (sestamibi)
- stress with either treadmill or IV vasodilator stress [dipyridamole (Persantine®), adenosine]
- images of the heart obtained during stress and at rest 3-4 h later
  - fixed defect: impaired perfusion at rest and during stress (infarcted/hibernating)
  - reversible defect: impaired perfusion only during stress (ischemic)

Most Commonly Used Treadmill Stress Test Protocols
- The Bruce Protocol: 7 stage test with each stage lasting 3 min. With each successive stage, the treadmill increases in both speed and gradient
- The Modified Bruce, Modified Naughton Protocol: for older individuals or those with limited exercise capacity

Important Contraindications to Exercise Testing
- Acute MI, aortic dissection, pericarditis, myocarditis, PE
- Severe AS, arterial HTN
- Inability to exercise adequately

Important Prognostic Factor

Duke Treadmill Score (DTS)
- Duke Treadmill Score (DTS)
- Important Prognostic Factor

Weighted Index Score:
- Weighted Index Score:
- Treadmill exercise time using standard Bruce protocol
- Maximum net ST segment deviation (depression or elevation)
- Exercise-induced angina provides diagnostic and prognostic information (such as 1-yr mortality)
- DTS = exercise time – (5 x MaxST) – (4 x angina index)

Am J Cardiol 1987;60:793-800

Patients with normal imaging (nuclear perfusion or stress echo) studies at peak stress have a <1% yr incidence of death or nonfatal MI and are thus often spared further invasive evaluation.
Cardiac Diagnostic Tests

- tracers
  - thallium-201 ($^{201}$Tl, a K$^+$ analogue)
  - technetium-99 ($^{99}$Tc)-labelled tracer (sestamibi/Cardiolite® or hexamibi/Myoview®)

**STRESS ECHOCARDIOGRAPHY**
- see Stress Echocardiography, C10

**INDICATIONS FOR STRESS TESTING**
- exercise ECG
  - initial evaluation in patients who are able to exercise
- exercise stress echo
  - when ECG is uninterpretable
  - intermediate pre-test probability with normal/equivocal exercise ECG
  - post-ACS when used to decide on potential efficacy of revascularization
  - to evaluate the clinical significance of valvular heart disease
- dobutamine stress echo (DSE)
  - among patients unable to exercise; same indications as exercise stress echo
  - low dose DSE can be used to assess myocardial viability and for assessing aortic stenosis with LV systolic dysfunction
- exercise MPI
  - when ECG is uninterpretable
  - intermediate pre-test probability with normal/equivocal exercise ECG
  - in patients with previous imaging whose symptoms have changed
  - to diagnose ischemia
- dipyridamole/adenosine MPI
  - to diagnose CAD in possible ACS patients with non-diagnostic ECG and negative serum biomarkers
  - when ECG is uninterpretable due to LBBB or V-paced rhythm
  - among patients unable to exercise, with the same indications as exercise MPI

---

**Cardiac Catheterization and Angiography**

- risks of procedure related complications: vascular injury, renal failure, stroke, MI
- mortality rate 0.1-0.2%
- invasive: catheters are introduced percutaneously into arterial and venous circulation under conscious sedation and contrast is injected
- arterial access most commonly through the femoral artery; radial approach gaining favour especially for obese patients and outpatients dependent on driving and ambulation
- venous access through the femoral vein or internal jugular vein
- same day procedure as outpatient
- indications for prehospitalization: anticoagulation, renal failure, diabetes, contrast allergy
- catheterization permits direct measurement of intracardiac pressures, transvalvular and mean peak pressure gradients, valve areas, cardiac output, shunt data, oxygen saturations, and visualization of coronary arteries, cardiac chambers and great vessels
- angiography may provide valuable information regarding lesion severity, complexity, location and prognosis

**Right Heart Catheterization (Swan-Ganz Catheter)**
- right atrial, right ventricular, and pulmonary artery pressures are recorded
- pulmonary capillary wedge pressure (PCWP)
  - obtained by advancing the catheter to wedge in the distal pulmonary artery
  - records pressure measured from the pulmonary venous system
  - in the absence of pulmonary venous disease reflects left atrial pressure

**Left Heart Catheterization**
- systolic and end-diastolic pressure tracings recorded; LV size, wall motion and ejection fraction can be assessed by injecting contrast into the LV (left ventriculography) via femoral/radial artery catheterization
- cardiac output (measured by the Fick oxygen method or the indicator dilution method)

---

ACC/AHA 2009 Guidelines for Use of Nuclear Testing
Stable angina, baseline ECG abnormalities, post-revascularization assessment, heart failure, patients unable to exercise, preoperative risk assessment for patients undergoing noncardiac surgery.

**Sensitivity and Specificity of Various Stress Testing**
- Exercise ECG (Sn 88; Sp 77)
- Stress Echocardiography (Sn 76; Sp 88)
- PET scanning (Sn 91; Sp 82)
- MIBI scanning (Sn 88; Sp 77)
Coronary Angiography
- coronary vasculature accessed via the coronary ostia
- contraindicated in severe renal failure (due to contrast agent toxicity) must check renal status

Diagnostic Catheterization
- complications for diagnostic catheterization <1%
- inadequate diagnostic procedures occur in fewer than 1% of cases
- provocative pharmacological agents can be used to unmask pathology
  - fluid loading may unmask latent pericardial constriction
  - afterload reduction or inotropic stimulation may be used to increase the outflow tract gradient in HCM
  - coronary vasoreactive agents (e.g. methylergonovine, acetylcholine)
  - a variety of pulmonary vasoreactive agents in primary pulmonary HTN (e.g. oxygen, calcium channel blockers, adenosine, nitric oxide, or prostacyclin)

Contrast-Enhanced CT Coronary Angiography
- fast ECG-synchronized multi-slice CT image acquisition in the heart has enabled non-invasive imaging of the coronary arterial tree
- often used to assess coronary artery and previous graft stenosis/viability that could not be seen during coronary angiography
- sensitivity = 85%, specificity = 90% for the diagnosis of obstructive coronary disease with >50% stenosis

Magnetic Resonance Imaging (MRI)
- offers high spatial resolution, eliminates the need for iodinated contrast, and does not involve exposure to ionizing radiation
- valuable in assessment of congenital cardiac anomalies, abnormalities of the aorta, and assessment of viable myocardium

CARDIAC DISEASE

Arrhythmias

Mechanisms of Arrhythmias

(I) Alterations in Impulse Formation
A. Abnormal Automaticity
- automaticity is a property of certain cardiomyocytes to depolarize to their threshold voltage to spontaneously generate action potentials in a rhythmical fashion
- under normal circumstances only cells in the specialized conduction system (SA node, AV node and ventricular conduction system) exhibit natural automaticity. These cells are pacemaking cells. The automaticity of these cells can become abnormally increased or decreased
in disease (e.g. post-MI ventricular ischemia) cells in the myocardium outside the conduction system may inappropriately acquire the property of automaticity and contribute to abnormal depolarization. If these ectopic generators depolarize at a rate that is greater than the SA node, they assume pacemaking control and become the source of abnormal rhythm.

Automaticity can be influenced by:
- neurohormonal tone (sympathetic and parasympathetic stimulation)
- abnormal metabolic conditions (hypoxia, acidosis, hypothermia)
- electrolyte abnormalities
- drugs (e.g. digitalis)
- local ischemia/infarction
- other cardiac pathology

This mechanism is responsible for the accelerated idioventricular rhythm and ventricular tachycardia that often occurs 24 to 72 h post MI.

B. Triggered Activity due to Afterdepolarizations
1. Early Afterdepolarizations
   - occur in the context of action potential prolongation
   - consequence of the membrane potential becoming more positive during repolarization
   - result in self-maintaining depolarizing oscillations of action potential, generating a tachyarrhythmia
   - basis for the degeneration of QT prolongation, either congenital or acquired, into Torsades de Pointes

2. Delayed Afterdepolarizations
   - occur after the action potential has fully repolarized, but before the next usual action potential, thus called a delayed afterdepolarization
   - commonly occurs in situations of high intracellular calcium (digitalis intoxication, ischemia) or during enhanced catecholamine stimulation

II) Alterations in Impulse Conduction
A. Re-Entry Circuits
   - the presence of self-sustaining re-entry circuit causes rapid repeated depolarizations in a region of myocardium
   - e.g. myocardium that is infarcted/ischemic will consist of non-excitable and partially excitable zones which will promote the formation of re-entry circuits

B. Conduction Block
   - ischemia, fibrosis, trauma, and drugs can cause transient, permanent, unidirectional or bidirectional block
   - most common cause of block is due to refractory myocardium (cardiomyocytes are in refractory period or zone of myocardium unexcitable due to fibrosis)
   - if block occurs along the specialized conduction system distal zones of the conduction system can assume pacemaking control
   - conduction block can lead to bradycardia or tachycardia when impaired conduction leads to re-entry phenomenon

C. Bypass Tracts
   - normally the only conducting tract from the atria to the ventricles is the AV node
   - congenital/acquired accessory conducting tracts bypass the AV node and facilitate premature ventricular activation before normal AV node conduction
   - see Pre-Excitation Syndromes, C18

---

**Figure 17. Clinical approach to arrhythmias**

- **Bradycardiacs (<60 bpm)**
  - Sinus bradycardia
  - Sinoatrial block
  - Sinus arrest
  - AV block (2nd and 3rd degree)
  - Junctional rhythm
  - Idioventricular rhythm

- **Tachyarrhythmias (>100 bpm)**

  **Regular**
  - Narrow QRS (SVTs)
    - Sinus tachycardia
    - Atrial tachycardia
    - Junctional tachycardia
    - AVNRT
    - AVRT (orthodromic)
    - Atrial flutter
  - Wide QRS
    - SVT with aberrancy/BBB
    - Atrial flutter with variable block
  - Atrial fibrillation

  **Irregular**
  - Narrow QRS (SVTs)
    - Atrial fibrillation
    - Ventricular tachycardia
    - AVRT (antidromic)
    - Premature atrial contraction
    - Polymorphic VT (torsades)
    - Premature ventricular contraction
  - Wide QRS
    - Atrial fibrillation with BBB
    - A. flutter with BBB and variable block
Bradyarrhythmias

SA NODAL DYSFUNCTION

Sinus Bradycardia
- P axis normal (P waves positive in I and aVF)
- rate <60 bpm
- marked sinus bradycardia (<50 bpm) may be seen in normal adults, particularly athletes, and in elderly individuals
- caused by
  - increased vagal tone or vagal stimulation
  - vomiting
  - episodes of myocardial ischemia or infarction (inferior MI)
  - sick sinus syndrome
  - increased intracranial pressure
  - hypothyroidism
  - hypothermia
  - drugs (β-blockers, calcium channel blockers, etc.)
- treatment: if symptomatic, atropine during acute episodes; pacing for sick sinus syndrome; if drug-induced, reduction or withdrawal of drugs

Sinus Block, Pause, and Arrest
- three disorders involving the SA node; the sinus pacemaker fires but the impulse fails to depolarize the atrial myocardium resulting in no initial P wave (and consequently no QRS complex, ST segment, or T wave)
- sinus block (SA block), a complete block or failure of the sinus node to depolarize the atria; the block can last one or more cardiac cycles and is a multiple of the normal P-P interval
- sinus pause: a delay in the formation of a sinus impulse in the SA node resulting in a temporary pause (usually >3 s)
- sinus arrest: a longer delay in the formation of a sinus impulse in the SA node
  - there is no clear cut-off between sinus pause vs. arrest – if the pause lasts greater than 3x the normal P-P interval then it may be called an arrest
  - the P-P prolongation is not phasic or gradual (unlike sinus arrhythmia) and is not a multiple of the normal P-P interval (unlike sino-atrial block)
- escape beats or rhythm may occur:
  - atrial escape: P waves with abnormal morphology
  - junctional escape: P waves not seen, or follow the QRS (retrograde P), rate 40-60 bpm
  - ventricular escape: no P wave; wide, abnormal QRS; slow rate 20-40 bpm

Sick Sinus Syndrome
- characterized by sinus node dysfunction (marked bradycardia, sinus pause/arrest, sinoatrial block)
  - when symptomatic, electronic pacemaker is indicated
  - frequently associated with episodes of atrial tachyarrhythmias ("tachy-brady syndrome")
  - usually require a combination of a pacemaker for bradycardia and medications (β-blocker, calcium channel blocker, and/or digoxin, initiated after pacemaker insertion) for tachycardia

AV Conduction Blocks

First Degree AV Block
- prolonged PR interval (>200 msec)
- frequently found among otherwise healthy adults
- no treatment required

Second Degree AV Block
- some of the atrial impulses are not conducted to the ventricles
- can describe block by ratio of number of P waves to number of QRS (e.g. 2:1, 3:1, 4:1 increases in severity)
- second degree AV block is further subdivided into Type I and Type II block:
  - Type I (Mobitz I) second degree AV block
    - a gradual prolongation of the PR interval precedes the failure of conduction of a P wave (Wenckebach phenomenon)
    - AV block is usually in AV node (proximal)
      - triggers (usually reversible): increased vagal tone (e.g. following surgery), RCA-mediated ischemia
      - not an indication for temporary or permanent pacing
Type II (Mobitz II) second degree AV block
- the PR interval is constant; there is an abrupt failure of conduction of a P wave
- AV block is usually distal to the AV node (i.e. His bundle)
- increased risk of high grade or 3rd degree AV block

2:1 AV Block
- often not possible to determine whether the block is type I or type II
- prolonged or repeated recordings may clarify the diagnosis

Third Degree AV Block
- complete failure of conduction of the supraventricular impulses to the ventricles
- ventricular depolarization initiated by an escape pacemaker distal to the block
- QRS can be narrow or wide (junctional vs. ventricular escape rhythm)
- P-P and R-R intervals are constant, variable PR intervals
- no relationship between P waves and QRS complexes (P waves “marching through”)
- management (see Electrical Pacing, C21)

Supraventricular Tachyarrhythmias

Presentation for SVT (and pre-excitation syndromes)
- presentation can include: palpitations, dizziness, dyspnea, chest discomfort, presyncope/syncope
- may precipitate congestive heart failure (CHF), hypotension or ischemia in patients with underlying disease
- untreated tachycardias can cause cardiomyopathy (rare, potentially reversible with treatment of SVTs)
- includes supraventricular and ventricular rhythms

Supraventricular Tachyarrhythmias (SVT)
- tachyarrhythmias that originate in the atria or AV junction
- this term is used when a more specific diagnosis of mechanism and site of origin cannot be made
- characterized by narrow QRS, unless there is pre-existing bundle branch block or aberrant ventricular conduction (abnormal conduction due to a change in cycle length)

Sinus Tachycardia
- sinus rhythm with rate >100 bpm
- occurs in normal subjects with increased sympathetic tone (exercise, emotions, pain), alcohol use, caffeinated beverages, drugs (e.g. β-adrenergic agonists, anticholinergic drugs, etc.)
- etiology: fever, hypotension, hypovolemia, anemia, thyrotoxicosis, CHF, MI, shock, PE, etc.
- treatment: treat underlying disease; consider β-blocker if symptomatic, calcium channel blocker if β-blockers contraindicated
Atrial Fibrillation (AFib)
- irregular rhythm caused by presence of 3 or more atrial foci (may mimic AFib)
- atrial rate 100-200 bpm, at least 3 distinct P wave morphologies and PR intervals vary, some P waves may not be conducted
- occurs more commonly in patients with COPD, and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline or digitalis toxicity
- treatment: treat the underlying cause; calcium channel blockers may be used (e.g. diltiazem, verapamil), β-blockers may be contraindicated because of severe pulmonary disease
- no role for electrical cardioversion, antiarrhythmics or ablation

Multifocal Atrial Tachycardia (MAT)
- irregular rhythm caused by presence of 3 or more atrial foci
- atrial rate 100-200 bpm, at least 3 distinct P wave morphologies and PR intervals vary, some P waves may not be conducted
- occurs more commonly in patients with COPD, and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline or digitalis toxicity
- treatment: treat the underlying cause; calcium channel blockers may be used (e.g. diltiazem, verapamil), β-blockers may be contraindicated because of severe pulmonary disease
- no role for electrical cardioversion, antiarrhythmics or ablation

Atrial Flutter
- rapid, regular atrial depolarization from a macro re-entry circuit within the atrium (most commonly the right atrium)
- atrial rate 250-350 bpm, usually 300 bpm
- AV block usually occurs; it may be fixed (2:1, 3:1, 4:1, etc.) or variable
- etiology: CAD, thyrotoxicosis, mitral valve disease, cardiac surgery, COPD, PE, pericarditis
- ECG: sawtooth flutter waves (most common type of flutter) in inferior leads (II, III, aVF); narrow QRS (unless aberrancy) (see Figure 22)
- in atrial flutter with 2:1 block, carotid sinus massage (first check for bruits), Valsalva maneuver, or adenosine may decrease AV conduction and bring out flutter waves
- treatment
  - acute: if unstable (e.g. hypotension, CHF, angina): electrical cardioversion
  - if stable
    1) rate control: β-blocker, diltiazem, verapamil, or digoxin
    2) chemical cardioversion: sotalol, amiodarone, type I antiarrhythmics, or electrical cardioversion
  - anticoagulation guidelines same as for patients with AFib (see Atrial Fibrillation, below)
  - long-term: antiarrhythmics, catheter radiofrequency (RF) ablation (success rate dependent on site of origin of atrial flutter)

Atrial Fibrillation (AFib)
- see CCS Atrial Fibrillation Guidelines 2012 for details (free mobile apps available on iOS, Android and Blackberry)
- most common sustained arrhythmia
- incidence increases with age (10% of population >80 yr old)
- symptoms: palpitations, fatigue, syncope, may precipitate or worsen heart failure
- classification:
  - chronic/permanent: continuous atrial fibrillation that is unresponsive to cardioversion; cardioversion will not be attempted
  - lone: occurs in persons younger than 60 yr and in whom no clinical or echocardiographic causes are found
  - nonvalvular: not caused by valvular disease, prosthetic heart valves, or valve repair
  - paroxysmal: episodes that terminate spontaneously
  - persistent: atrial fibrillation sustained for more than 7 d or atrial fibrillation that terminates only with cardioversion
  - recurrent: two or more episodes of atrial fibrillation
  - secondary: caused by a separate underlying condition or event (e.g. myocardial infarction, cardiac surgery, pulmonary disease, hyperthyroidism)
  - may be associated with thromboembolic events (4%/yr in nonvalvular AFib)

- initiation
  - single circuit re-entry and/or ectopic foci act as aberrant generators producing atrial tachycardia (350-600 bpm)
  - impulses conduct irregularly across the atrial myocardium to give rise to fibrillation
  - in some cases, ectopic foci have also been mapped to the pulmonary vein ostia and can be ablated

- maintenance
  - the tachycardia causes atrial structural and electrophysiological remodelling changes that further promote AFib; the longer the patient is in AFib the more difficult it is to convert back to sinus rhythm

- consequences
  - the AV node irregularly filters incoming atrial impulses producing an irregular ventricular response of <200 bpm and the tachycardia leads to suboptimal cardiac output
  - fibrillatory conduction of the atria promotes blood stasis increasing the risk of thrombus formation – AFib is an important risk factor for stroke

Premature Beats
- premature atrial contraction (PAC) (Figure 27)
  - ectopic supraventricular beat originating in the atria
  - P wave morphology of the PAC usually differs from that of a normal sinus beat
  - junctional premature beat
  - ectopic supraventricular beat that originates in the vicinity of the AV node
  - P wave is usually not seen or an inverted P wave is seen and may be before or closely follow the QRS complex
  - treatment usually not required

Multifocal Atrial Tachycardia (MAT)
- occurs more commonly in patients with COPD, and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline or digitalis toxicity
- treatment: treat the underlying cause; calcium channel blockers may be used (e.g. diltiazem, verapamil), β-blockers may be contraindicated because of severe pulmonary disease
- no role for electrical cardioversion, antiarrhythmics or ablation

Atrial Flutter
- rapid, regular atrial depolarization from a macro re-entry circuit within the atrium (most commonly the right atrium)
- atrial rate 250-350 bpm, usually 300 bpm
- AV block usually occurs; it may be fixed (2:1, 3:1, 4:1, etc.) or variable
- etiology: CAD, thyrotoxicosis, mitral valve disease, cardiac surgery, COPD, PE, pericarditis
- ECG: sawtooth flutter waves (most common type of flutter) in inferior leads (II, III, aVF); narrow QRS (unless aberrancy) (see Figure 22)
- in atrial flutter with 2:1 block, carotid sinus massage (first check for bruits), Valsalva maneuver, or adenosine may decrease AV conduction and bring out flutter waves
- treatment
  - acute: if unstable (e.g. hypotension, CHF, angina): electrical cardioversion
  - if stable
    1) rate control: β-blocker, diltiazem, verapamil, or digoxin
    2) chemical cardioversion: sotalol, amiodarone, type I antiarrhythmics, or electrical cardioversion
  - anticoagulation guidelines same as for patients with AFib (see Atrial Fibrillation, below)
  - long-term: antiarrhythmics, catheter radiofrequency (RF) ablation (success rate dependent on site of origin of atrial flutter)

Atrial Fibrillation (AFib)
- see CCS Atrial Fibrillation Guidelines 2012 for details (free mobile apps available on iOS, Android and Blackberry)
- most common sustained arrhythmia
- incidence increases with age (10% of population >80 yr old)
- symptoms: palpitations, fatigue, syncope, may precipitate or worsen heart failure
- classification:
  - chronic/permanent: continuous atrial fibrillation that is unresponsive to cardioversion; cardioversion will not be attempted
  - lone: occurs in persons younger than 60 yr and in whom no clinical or echocardiographic causes are found
  - nonvalvular: not caused by valvular disease, prosthetic heart valves, or valve repair
  - paroxysmal: episodes that terminate spontaneously
  - persistent: atrial fibrillation sustained for more than 7 d or atrial fibrillation that terminates only with cardioversion
  - recurrent: two or more episodes of atrial fibrillation
  - secondary: caused by a separate underlying condition or event (e.g. myocardial infarction, cardiac surgery, pulmonary disease, hyperthyroidism)
  - may be associated with thromboembolic events (4%/yr in nonvalvular AFib)

- initiation
  - single circuit re-entry and/or ectopic foci act as aberrant generators producing atrial tachycardia (350-600 bpm)
  - impulses conduct irregularly across the atrial myocardium to give rise to fibrillation
  - in some cases, ectopic foci have also been mapped to the pulmonary vein ostia and can be ablated

- maintenance
  - the tachycardia causes atrial structural and electrophysiological remodelling changes that further promote AFib; the longer the patient is in AFib the more difficult it is to convert back to sinus rhythm

- consequences
  - the AV node irregularly filters incoming atrial impulses producing an irregular ventricular response of <200 bpm and the tachycardia leads to suboptimal cardiac output
  - fibrillatory conduction of the atria promotes blood stasis increasing the risk of thrombus formation – AFib is an important risk factor for stroke

AFib on ECG
- no organized P waves due to rapid atrial activity (350-600 bpm) causing a chaotic fibrillatory baseline
- irregularly irregular ventricular response (typically 100-180 bpm), narrow QRS (unless aberrancy or previous BBB)
- wide QRS complexes due to aberrancy may occur following a long-short cycle sequence ("Ashman phenomenon")
- loss of atrial contraction, thus no "a" wave seen in JVP, no S4 on auscultation

Management (adapted from CCS Atrial Fibrillation Guidelines 2012)
**Major objectives (RACE):** all patients with AF (paroxysmal, persistent, or permanent), should be stratified using a predictive index for stroke risk and for the risk of bleeding, and most patients should receive either an oral anticoagulant or ASA (see Table 3)

1. Rate control: β-blockers, diltiazem, verapamil (in patients with heart failure: digoxin, amiodarone)
2. Anticoagulation: use either warfarin, dabigatran, rivaroxaban, apixaban to prevent thromboembolism
3. Cardioversion (electrical)
   - if AFib <24-48 h, can usually cardiovert without anticoagulation
   - if AFib >24-48 h, anticoagulate for 3 wk prior and 4 wk after cardioversion
   - if patient unstable (hypotensive, active angina due to tachycardia, uncontrolled heart failure) should cardiovert immediately
4. Etiology
   - HTN, CAD, valvular disease, pericarditis, cardiomyopathy, myocarditis, ASD, post-operative, PE, COPD, thyrotoxicosis, sick sinus syndrome, alcohol ("holiday heart")
   - may present in young patients without demonstrable disease ("lone AFib") and in the elderly without underlying heart disease

Additional Management Points Regarding AFib
- studies of patients with AFib suggest that there is no difference in long-term survival when treating patients with a rhythm-control versus rate-control strategy
- however, many patients with a significant underlying structural heart lesion (e.g. valve disease, cardiomyopathy) will not tolerate AFib well (since may be dependent on atrial kick) and these patients should be cardioverted (chemical or electrical) as soon as possible

Newly Discovered AFib
- anticoagulants may be beneficial if high risk for stroke
- if the episode is self-limited and not associated with severe symptoms, no need for antiarrhythmic drugs
- if AFib persists, 2 options:
  1. rate control and anticoagulation (as indicated above)
  2. cardioversion (as above)

Recurrent AFib/Permanent AFib
- if episodes are brief or minimally symptomatic, antiarrhythmic drugs may be avoided; rate control and anticoagulation are appropriate
- patients who have undergone at least one attempt to restore sinus rhythm may remain in AFib after recurrence: permanent AFib may be accepted (with rate control and antithrombotics as indicated by CHADS2 score) in certain clinical situations
• if symptoms are bothersome or episodes are prolonged, antiarrhythmic drugs should be used
  ▪ no or minimal heart disease: flecainide, propafenone or sotalol
  ▪ LV dysfunction: amiodarone
  ▪ CAD: β-blockers, amiodarone

**AV Nodal Re-Entrant Tachycardia (AVNRT)**
- re-entrant circuit using dual pathways (fast conducting β-fibres and slow conducting α-fibres) within or near the AV node; often found in the absence of structural heart disease – cause is commonly idiopathic, although familial AVNRT has been reported
- sudden onset and offset
- fast regular rhythm: rate 150-250 bpm
- usually initiated by a supraventricular or ventricular premature beat
- AVNRT accounts for 60-70% of all paroxysmal SVTs
- retrograde P waves may be seen but are usually lost in the QRS complex (see Figure 24)
- treatment
  ▪ acute: Valsalva or carotid massage, adenosine is first choice if unresponsive to vagal maneuvers; if no response, try metoprolol, digoxin, diltiazem, electrical cardioversion if patient hemodynamically unstable (hypotension, angina or CHF)
  ▪ long-term: 1st line – β-blocker, diltiazem, digoxin; 2nd line – flecainide, propafenone; 3rd line – catheter ablation

**Pre-Excitation Syndromes**
- refers to a subset of SVTs mediated by an accessory pathway which can lead to ventricular pre-excitation

**Wolff-Parkinson-White (WPW) Syndrome**
- congenital defect present in 1.5-2/1000 of the general population
- an accessory conduction tract (Bundle of Kent; can be in right or left atrium) abnormally allows early electrical activation of part of one ventricle
- impulses travel at a greater conduction velocity across the Bundle of Kent thereby effectively ‘bypassing’ AV node
- since the ventricles are activated earlier, the ECG shows early ventricular depolarization in the form of initial slurring of the QRS complex – the so-called “delta wave”
- atrial impulses that conduct to the ventricles through both the Bundle of Kent and the normal AV node/His-Purkinje system generate a broad “fusion complex”
- ECG features of WPW
  ▪ PR interval <120 msec
  ▪ delta wave: slurred upstroke of the QRS (the leads with the delta wave vary with site of bypass)
  ▪ widening of the QRS complex due to premature activation
  ▪ secondary ST segment and T wave changes
  ▪ tachyarrhythmias may occur – most often AVRT and AFib

© Laura E. Smith 2012
Figure 24. AVNRT

© Young M. Kim 2011
Figure 25. Mechanism for AVNRT

© Young M. Kim 2011
Figure 26. Accessory pathway conduction in WPW causes early ventricular activation leading to the appearance of a delta wave (slurred upstroke of the QRS) on the ECG before usual conduction occurs across the AV node.
AFib in WPW Patients
- AFib is the index arrhythmia in up to 20% of patients with WPW syndrome
  - it is usually intermittent rather than persistent or permanent
- rapid atrial depolarizations in AFib are conducted through the bypass tract which is not able to filter impulses like the AV node can
- consequently the ventricular rate becomes extremely rapid (>200 bpm) and the QRS complex widens
- treatment: electrical cardioversion, IV procainamide or IV amiodarone
  - do not use drugs that slow AV node conduction (digoxin, β-blockers) as this may cause preferential conduction through the bypass tract and precipitate VF
- long-term: ablation of bypass tract if possible

AV Re-Entrant Tachycardia (AVRT)
- re-entrant loop via accessory pathway and normal conduction system
- initiated by a premature atrial or ventricular complex
- orthodromic AVRT: stimulus from a premature complex travels up the bypass tract (V to A) and down the AV node (A to V) with narrow QRS complex (no delta wave because stimulus travels through normal conduction system) (see Figure 28)
  - comprises 95% of the reentrant tachycardias associated with WPW syndrome
- antidromic AVRT: more rarely the stimulus goes up the AV node (V to A) and down the bypass tract (A to V); wide and abnormal QRS as ventricular activation is only via the bypass tract
- treatment
  - acute: similar to AVNRT except avoid long-acting AV nodal blockers, e.g. digoxin and verapamil
  - long-term: for recurrent arrhythmias ablation of the bypass tract is recommended
  - drugs such as flecainide and procainamide can be used

Ventricular Tachyarrhythmias

Premature Ventricular Contraction (PVC) or Ventricular Premature Beat (VPB)
- QRS width >120 msec, no preceding P wave, bizarre QRS morphology
- origin: LBBB morphology of VT = RV origin; RBBB morphology of VT = LV origin
- PVCs may be benign but are usually significant in the following situations:
  - consecutive (≥3 = VT) or multiform (varied origin)
  - PVC falling on the T wave of the previous beat (“R on T phenomenon”): may precipitate ventricular tachycardia or VF

Accelerated Idioventricular Rhythm
- ectopic ventricular rhythm with rate 50-100 bpm
- more frequently occurs in the presence of sinus bradycardia and is easily overdriven by a faster supraventricular rhythm
- frequently occurs in patients with acute MI or other types of heart disease (cardiomyopathy, hypertensive, valvular) but it does not affect prognosis and does not usually require treatment

Ventricular Tachycardia (VT)
- 3 or more consecutive ectopic ventricular complexes (Figure 29)
  - rate >100 bpm (usually 140-200)
  - ventricular flutter: if rate >200 bpm and complexes resemble a sinusoidal pattern
  - “sustained VT” if it lasts longer than 30 s
  - ECG characteristics: wide regular QRS tachycardia (QRS usually >140 msec);
  - AV dissociation; bizarre QRS pattern. Also favour Dx of VT: left axis or right axis deviation, nonspecific intraventricular block pattern, monophasic or biphasic QRS in V1 with RBBB, QRS concordance in V1-V6
  - occasionally during VT supraventricular impulses may be conducted to the ventricles generating QRS complexes with normal or aberrant supraventricular morphology (“ventricular capture”) or summation pattern (“fusion complexes”)
- monomorphic VT
  - identical complexes with uniform morphology
  - more common than polymorphic VT
  - typically result from intraventricular re-entry circuit
  - potential causes: chronic infarct scarring, acute MI/ischemia, cardiomyopathies, myocarditis, arrhythmogenic right ventricular dysplasia, idiopathic, drugs (e.g. cocaine), electrolyte disturbances
- polymorphic VT
  - complexes with constantly changing morphology, amplitude, and polarity
  - more frequently associated with hemodynamic instability due to faster rates (typically 200-250 bpm) vs. monomorphic VT
  - potential causes: acute MI, severe or silent ischemia, and predisposing factors for QT prolongation (see Torsades de Pointes, C20)
• treatment
  ▪ sustained VT (>30 s) is an emergency, requiring immediate treatment
  ▪ hemodynamic compromise: electrical cardioversion
  ▪ no hemodynamic compromise: electrical cardioversion, lidocaine, amiodarone, type 1a agents (procainamide, quinidine)

Figure 29. Ventricular tachycardia (monomorphic)

*If patient >65 and previous MI or structural heart disease, then chance of VT >95%
**May terminate VT in some patients with no structural heart disease

Torsades de Pointes
• a variant of polymorphic VT that occurs in patients with baseline QT prolongation – “twisting of the points” (Figure 30)
• looks like usual VT except that QRS complexes “rotate around the baseline” changing their axis and amplitude
• ventricular rate >100 bpm, usually 150-300 bpm
• etiology: predisposition in patients with prolonged QT intervals
  ▪ congenital long QT syndromes
  ▪ drugs: e.g. class IA (quinidine), class III (sotalol), phenothiazines (TCAs), erythromycin, quinolones, antihistamines
  ▪ electrolyte disturbances: hypokalemia, hypomagnesemia
  ▪ nutritional deficiencies causing above electrolyte abnormalities
• treatment: IV magnesium, temporary pacing, isoproterenol and correct underlying cause of prolonged QT, electrical cardioversion if hemodynamic compromise

Figure 30. Torsades de pointes

Ventricular Fibrillation (VFib)
• chaotic ventricular arrhythmia, with very rapid irregular ventricular fibrillatory waves of varying morphology (Figure 31)
• terminal event, unless advanced cardiac life-support (ACLS) procedures are promptly initiated to maintain ventilation and cardiac output, and electrical defibrillation is carried out
• most frequent cause of sudden death
• refer to ACLS algorithm for complete therapeutic guidelines

Figure 31. Ventricular fibrillation
**Electrophysiology (EPS) Studies**

- invasive test for the investigation and treatment of cardiac rhythm disorders using intracardiac catheters
- provide detailed analysis of the arrhythmia mechanism and precise site of origin when ECG data are nondiagnostic or unobtainable
- bradyarrhythmias: define the mechanisms of SA node dysfunction and localize site of AV conduction block
- tachyarrhythmias: map for possible ablation or to assess inducibility of ventricular tachycardia

**Electrical Pacing**

- the decision to implant a pacemaker usually is based on symptoms of a bradyarrhythmia or tachyarrhythmia in the setting of heart disease

**Pacemaker Indications**

- SA node dysfunction (most common): symptomatic bradycardia ± hemodynamic instability
- common manifestations include: syncope, presyncope, or severe fatigue
- SA node dysfunction is commonly caused by: intrinsic disease within the SA node (e.g. idiopathic degeneration, fibrosis, ischemia, or surgical trauma), abnormalities in autonomic nervous system function, and drug effects
- AV nodal-infranodal block: Mobitz II, complete heart block

**Pacemaker Complications**

- complications related to surgical implantation include venous access (pneumothorax, hemothorax, air embolism), pacemaker leads (perforation, malposition), pocket hematomas and infection
- complications specific to the pacemaker include a failure to pace, failure to sense, pulse generator failure, pacemaker syndrome and pacemaker mediated tachycardia

**Pacing Techniques**

- temporary: transvenous (jugular, subclavian, femoral) or external pacing
- permanent: transvenous into RA, apex of RV or both
- can sense and pace atrium, ventricle or both
- new generation: rate responsive, able to respond to physiologic demand
- biventricular

**Implantable Cardioverter Defibrillators (ICDs)**

- sudden cardiac death (SCD) usually results from ventricular fibrillation (VFib), sometimes preceded by monomorphic or polymorphic ventricular tachycardia (VT)
- ICDs detect ventricular tachyarrhythmias and are highly effective in terminating VT/VFib and in aborting SCD
- mortality benefit vs. antiarrhythmics in secondary prevention
- benefit seen in patients with ischemic and non-ischemic cardiomyopathy, depressed left ventricular ejection fraction (LVEF), prolonged QRS
- see Heart Failure, C30 for current treatment recommendations

**Catheter Ablation**

**Techniques**

- radiofrequency (RF) energy: a low-voltage high-frequency form of electrical energy (similar to cautery). RF energy produces small, homogeneous, necrotic lesions approximately 5-7 mm in diameter and 3-5 mm in depth

**Indications**

- paroxysmal SVT
  - AVNRT: accounts for more than half of all cases
- accessory pathway (orthodromic reciprocating tachycardia): 30% of SVT
  - re-entrant rhythm, with an accessory AV connection as the retrograde limb
  - corrected by targeting the accessory pathway
- atrial flutter: flutter focus in RA
- AFib: potential role for pulmonary vein ablation
- ventricular tachycardia: focus arises from the right ventricular outflow tract and less commonly originates in the inferoseptal left ventricle near the apex (note: majority of cases of VT are due to scarring from previous MI and cannot be ablated)
Major Complications

- 1% of patients
- death: 0.1-0.2%
- cardiac: high grade AV block requiring permanent pacemaker, tamponade, pericarditis
- vascular: hematoma, vascular injury, thromboembolism, TIA/stroke
- pulmonary: PE

Ischemic Heart Disease

Epidemiology

- most common cause of cardiovascular morbidity and mortality
- atherosclerosis and thrombosis are the most important pathogenetic mechanisms
- male:female ratio = 2:1 with all age groups included (Framingham study), 8:1 for age <40, 1:1 for age >70
- peak incidence of symptomatic IHD is age 50-60 (men) and 60-70 (women)
- for primary prevention of ischemic heart disease please see Family Medicine, FM19

* Major risk factor

Figure 32. Pathophysiology of atherosclerosis

Chronic Stable Angina

Definition

- symptom complex resulting from an imbalance between oxygen supply and demand in the myocardium

Etiology and Pathophysiology

- factors that decrease myocardial oxygen supply
  - decreased luminal diameter: atherosclerosis, vasospasm
  - decreased duration of diastole: tachycardia (decreased duration of diastolic coronary perfusion)
  - decreased hemoglobin: anemia
  - decreased $\text{SaO}_2$: hypoxemia
  - congenital anomalies

Chronic stable angina is most often due to a fixed stenosis caused by an atheroma.

Acute coronary syndromes are the result of plaque rupture.
• factors that increase myocardial oxygen demand
  • increased heart rate: hyperthyroidism
  • increased contractility: hyperthyroidism
  • increased wall stress: myocardial hypertrophy, aortic stenosis

**Signs and Symptoms**
• typical: retrosternal chest pain, tightness or discomfort radiating to left (± right) shoulder/arm/neck/jaw, associated with diaphoresis, nausea, anxiety
• predictably precipitated by the “3 Es”: exertion, emotion, eating
• brief duration, lasting <10-15 min and typically relieved by rest and nitrates
• Levine's sign: clenching fist over sternum when describing chest pain
• anginal equivalents: dyspnea, acute LV failure, flash pulmonary edema

**Clinical Assessment**
• history including directed risk factor assessment and physical exam
• labs: HB, fasting glucose, fasting lipid profile
• ECG (at rest and during episode of chest pain if possible)
• CXR (suspected heart failure, valvular disease, pericardial disease, aortic dissection/aneurysm, or signs or symptoms of pulmonary disease)
• stress testing (see Cardiac Diagnostic Tests, C5) or angiography
  ▪ to assess systolic murmur suggestive of aortic stenosis, mitral regurgitation and/or HCM
  ▪ to assess LV function in patients with Hx of prior MI, pathological Q waves, signs or symptoms of congestive heart failure (CHF)

**Differential Diagnosis**
• see Differential Diagnosis of Common Presentations, C4

**Treatment of Chronic Stable Angina**
1. **General measures**
   • goals: to reduce myocardial oxygen demand and/or increase oxygen supply
   • lifestyle modification (diet, exercise)
   • treatment of risk factors: statins (see Endocrinology, E5, Family Medicine, FM9 for target lipid guidelines), antihypertensives, etc.
2. **Antiplatelet therapy** (first-line therapy)
   • ASA
3. **β-blockers** (first-line therapy – decrease overall mortality)
   • increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)
   • cardioselective agents preferred (e.g. metoprolol, atenolol) to avoid peripheral effects (inhibition of vasodilation and bronchodilation via β2 receptors)
   • avoid intrinsic sympathomimetics (e.g. acebutolol) which increase demand
4. **Nitrates** (symptomatic control, no clear impact on survival)
   • decrease preload (venous dilatation) and afterload (arteriolar dilatation), and increase coronary perfusion
   • maintain daily nitrate-free intervals to prevent tolerance (tachyphylaxis)
5. **Calcium channel blockers** (CCBs, second-line or combination)
   • increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)
   • caution: verapamil/diltiazem combined with β-blockers may cause symptomatic sinus bradycardia or AV block
6. **ACE inhibitors** (ACEI, not used to treat symptomatic angina)
   • angina patients tend to have risk factors for CV disease which warrant use of an ACEI (e.g. hypertension, diabetes, proteinuric renal disease, previous MI with LV dysfunction)
   • benefit in all patients at high risk for CV disease (concomitant DM, renal dysfunction or LV systolic dysfunction)
   • angiotensin II receptor blockers (ARBs) can be used when ACEI contraindicated (e.g. hypersensitivity, angioedema)
7. **Invasive strategies**
   • revascularization (see Coronary Revascularization, C28 and COURAGE trial sidebar)

**VARIANT ANGINA** (Prinzmetal’s Angina)
• myocardial ischemia secondary to coronary artery vasospasm, with or without atherosclerosis
• uncommonly associated with infarction or LV dysfunction
• typically occurs between midnight and 8 AM, unrelated to exercise, relieved by nitrates
• typically ST elevation on ECG
• diagnosed by provocative testing with ergot vasoconstrictors (rarely done)
• treat with nitrates and CCBs

**SYNDROME X**
• typical symptoms of angina but normal angiogram
• may show definite signs of ischemia with exercise testing
• thought to be due to inadequate vasodilator reserve of coronary resistance vessels
• better prognosis than overt epicardial atherosclerosis

**Optimal Medical Therapy with or without PCI for Stable Coronary Disease. COURAGE Trial**
*Randomized, controlled trial with median follow-up of 4.6 yr.*
*Population: 2287 patients who had objective evidence of myocardial ischemia and significant stable coronary artery disease.*
*Intervention: Patients were randomized to receive intensive pharmacologic therapy and lifestyle intervention with or without percutaneous coronary intervention (PCI).*
*Outcome: Primary outcome was all-cause mortality and non-fatal myocardial infarction (MI). Secondary outcome had additional events of stroke, all MI, and hospitalization for unstable angina with negative biomarkers.*
*Results: There was no significant difference in primary (unadjusted hazard ratio: 1.05; p=0.62) or secondary outcomes (hazard ratio: 1.05; p=0.62) between the PCI and non-PCI intervention groups. The PCI group had significantly lower rates of subsequent revascularization at 4 yr of follow-up (hazard ratio 0.63, p<0.001) and was more angina-free in the first 4 yr of follow-up.*
*Conclusions: PCI is an adjunct in initial management in patients with significant stable coronary artery disease does not reduce mortality, MI, stroke or hospitalization for ACS, but does provide angina relief and reduced risk of revascularization.*
Acute Coronary Syndromes (ACS)

Definition
- ACS includes the spectrum of UA, NSTEMI and STEMI. This distinction aids in providing the appropriate therapeutic intervention
  - MI is defined by evidence of myocardial necrosis. It is diagnosed by a rise/fall of serum markers plus any one of:
    - symptoms of ischemia (chest/upper extremity/mandibular/epigastric discomfort; dyspnea)
    - ECG changes (ST-T changes, new BBB or pathological Q waves)
    - imaging evidence (myocardial loss of viability, wall motion abnormality or intracoronary thrombus)
  - if biomarker changes are unattainable, cardiac symptoms combined with new ECG changes is sufficient
  - NSTEMI meets criteria for myocardial infarction without ST elevation or BBB
  - STEMI meets criteria for myocardial infarction characterized by ST elevation or new BBB
- UA is clinically defined by any of the following:
  - accelerating pattern of pain: increased frequency, increased duration, decreased threshold of exertion, decreased response to treatment
  - angina at rest
  - new-onset angina
  - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])

Investigations
- history and physical
  - note that up to 30% of MIs are unrecognized or “silent” due to atypical symptoms – more common in women, DM, elderly, post-heart transplant (because of denervation)
- ECG
- CXR
- labs
  - serum cardiac biomarkers for myocardial damage (repeat 8 h later) (see Cardiac Biomarkers, C9)
  - CBC, INR/PTT, electrolytes and magnesium, creatinine, urea, glucose, serum lipids
  - draw serum lipids within 24-48 h because values are unreliable from 2-48 d post-MI

MANAGEMENT OF ACUTE CORONARY SYNDROMES

1. General measures
   - ABCs: assess and correct hemodynamic status first
   - bed rest, cardiac monitoring, oxygen
   - nitroglycerin SL followed by IV
   - morphine IV

2. Anti-platelet and anticoagulation therapy
   - ASA 162-325 mg chewed
   - NSTEMI
     - clopidogrel 300 mg loading dose, then 75 mg QD in addition to ASA or if ASA contraindicated, subcutaneous low molecular weight heparin or IV unfractionated heparin (UFH) (LMWH preferred, except in renal failure or if CABG is planned within 24 h)
     - if PCI is planned: clopidogrel 300 mg loading dose and IV GP IIb/IIIa inhibitor (e.g. abciximab)
     - anticoagulation options depend on reperfusion strategy:
       - primary PCI: UFH during procedure; bivalirudin is a possible alternative
       - thrombolysis: LMWH (enoxaparin) until discharge from hospital; can use UFH as alternative because of possible rescue PCI
       - no reperfusion: LMWH (enoxaparin) until discharge from hospital
     - continue LMWH or UFH followed by oral anticoagulation at discharge if at high risk for thromboembolic event (large anterior MI, AFib, severe LV dysfunction, CHF, previous DVT or PE, or echo evidence of mural thrombus)
   - STEMI
     - clopidogrel 300 mg loading dose, then 75 mg QD in addition to ASA or if ASA contraindicated, subcutaneous low molecular weight heparin or IV unfractionated heparin (UFH) (LMWH preferred, except in renal failure or if CABG is planned within 24 h)
     - if PCI is planned: clopidogrel 300 mg loading dose and IV GP IIb/IIIa inhibitor (e.g. abciximab)
     - anticoagulation options depend on reperfusion strategy:
       - primary PCI: UFH during procedure; bivalirudin is a possible alternative
       - thrombolysis: LMWH (enoxaparin) until discharge from hospital; can use UFH as alternative because of possible rescue PCI
       - no reperfusion: LMWH (enoxaparin) until discharge from hospital
     - continue LMWH or UFH followed by oral anticoagulation at discharge if at high risk for thromboembolic event (large anterior MI, AFib, severe LV dysfunction, CHF, previous DVT or PE, or echo evidence of mural thrombus)

3. β-blockers
   - first dose IV followed by oral administration
   - STEMI: contraindications include signs of heart failure, low output states, risk of cardiogenic shock, heart block, asthma or airway disease; initiate orally within 24 h of diagnosis when indicated
   - if β-blockers are contraindicated or if β-blockers/nitrates fail to relieve ischemia, non-dihydropyridine calcium channel blockers (e.g. diltiazem, verapamil) may be used as second-line therapy in the absence of severe LV dysfunction or pulmonary vascular congestion (calcium channel blockers do not prevent MI or decrease mortality)
4. Invasive strategies and reperfusion options

- **UA/NSTEMI**: early coronary angiography ± revascularization if possible is recommended with any of the following high-risk indicators:
  - recurrent angina/ischemia at rest despite intensive anti-ischemic therapy
  - CHF or LV dysfunction
  - hemodynamic instability
  - high (≥3) TIMI risk score (tool used to estimate mortality following an ACS)
  - sustained ventricular tachycardia
  - dynamic ECG changes
  - high-risk findings on non-invasive stress testing
  - PCI within the previous 6 mo
  - repeated presentations for ACS despite treatment and without evidence of ongoing ischemia or high risk features
  - note: thrombolysis is NOT administered for UA/NSTEMI

- **STEMI**
  - after diagnosis of STEMI is made, do not wait for results of further investigations before implementing reperfusion therapy
  - goal is to re-perfuse artery: thrombolysis (“EMS-to-needle”) within 30 min or primary PCI (“EMS-to-balloon”) within 90 min (depending on capabilities of hospital and access to hospital with PCI facility)
  - thrombolysis
    - preferred if patient presents ≤12 h of symptom onset, and <30 min after presentation to hospital, has contraindications to PCI, or PCI cannot be administered within 90 min
  - **PCI**
    - early PCI (≤12 h after symptom onset and <90 min after presentation) improves mortality vs. thrombolysis with fewer intra-cranial hemorrhages and recurrent MIs
    - rescue PCI: following failed thrombolytic therapy (diagnosed when following thrombolysis, ST segment elevation fails to resolve below half its initial magnitude and patient still having chest pain)

**Enoxaparin versus Unfractionated Heparin with Fibrinolysis for ST-elevation Myocardial Infarction**

*NEJM* 2006;354:1477-88

**Study:** Prospective multicenter RCT.

**Patients:** 20,479 patients (median age 60 yr. 77% male) with STEMI who were scheduled to undergo fibrinolysis.

**Intervention:** Patients were randomized to receive either enoxaparin or weight-based unfractionated heparin in addition to thrombolysis and standard therapies.

**Primary Outcome:** Death or recurrent nonfatal MI 30 d post-event.

**Results:** The composite primary outcome occurred less often in the enoxaparin group compared with those who received unfractionated heparin (9.9% vs. 12.0%, p < 0.001, NNT = 47). Taken separately, there was a trend toward reduced mortality (6.9% vs. 7.5%, p = 0.11) and a significant reduction in nonfatal reinfarction (3.0% vs. 4.5%, p < 0.001) in the enoxaparin group. The risk of major bleeding was significantly increased in the enoxaparin group (2.1% vs. 1.4%, p < 0.001, NNH = 142).

**Conclusion:** In patients with STEMI receiving thrombolysis, enoxaparin is superior to unfractionated heparin in preventing recurrent nonfatal MI and may lead to a small reduction in mortality.

Long-Term Management of ACS

• risk of progression to MI or recurrence of MI or death is highest within 1 mo
• at 1-3 mo after the acute phase, most patients resume a clinical course similar to that in patients with chronic stable coronary disease
• pre-discharge work-up: ECG and echo to assess residual LV systolic function
• drugs required in hospital to control ischemia should be continued after discharge in all patients
• other medications for long-term management of ACS are summarized below

1. General Measures
   • education
   • risk factor modification

2. Antiplatelet and Anticoagulation Therapy
   • ECASA 75-162 mg daily
   • clopidogrel 75 mg daily (at least 1 mo, up to 9-12 mo, if stent placed at least 12 mo)
   • prasugrel 10 mg daily or ticagrelor 90 mg twice daily can be used as alternatives to clopidogrel when indicated
   • ± warfarin x 3 mo if high risk (large anterior MI, LV thrombus, LVEF <30%, history of VTE, chronic AFib)

3. β-Blockers (e.g. metoprolol 25-50 mg bid or atenolol 50-100 mg daily)

4. Nitrates
   • alleviate ischemia but do not improve outcome
   • use with caution in right-sided MI patients who have become preload dependent

5. Calcium Channel Blockers (NOT recommended as first line treatment, consider as alternative to β-blockers)

6. Angiotensin-Converting Enzyme Inhibitors (ACEI)
   • prevent adverse ventricular remodelling
   • recommended for asymptomatic high-risk patients (e.g. diabetics), even if LVEF >40%
   • recommended for symptomatic CHF, reduced LVEF (<40%), anterior MI
   • use ARBs in patients who are intolerant of ACEI

7. ± Aldosterone Antagonists
   • if on ACEI and β-blockers and LVEF <40% and CHF or DM
   • significant mortality benefit shown with eplerenone by 30 d

8. Statins (early, intensive, irrespective of cholesterol level; e.g. atorvastatin 80 mg daily)

9. Invasive Cardiac Catheterization if indicated (risk stratification, see Figure 34)

Figure 34. Post-MI risk stratification

Prognosis following STEMI

• 5-15% of hospitalized patients will die
  • risk factors
    • infarct size/severity
    • age
    • co-morbid conditions
    • development of heart failure or hypotension
• post-discharge mortality rates
  • 6-8% within first year, half of these within first 3 months
  • 4% per year following first year
  • risk factors
    • LV dysfunction
    • residual myocardial ischemia
    • ventricular arrhythmias
    • history of prior MI

### Treatment Algorithm for Chest Pain

**Symptoms suggestive of an acute coronary syndrome**
- 1. 12-lead electrocardiogram
- 2. Aspirin
- 3. Supplemental oxygen
- 4. Sublingual nitroglycerin
- 5. Morphine PRN
- 6. Cardiac enzymes

**No ST-segment changes**
- Initial enzymes normal
- Observe:
  - 1. Nitroglycerin PRN
  - 2. Analgesia
  - 3. Serial ECG and cardiac enzymes

**No current chest pain**, **serial studies negative**
- Provocative stress testing
- Negative results
- Search for other causes of chest pain

**Provocative stress testing**
- Negative results
- Positive results

**Positive results**
- 1. GP IIb/IIIa inhibitor
- 2. Coronary angiography
- 3. Coronary revascularization

**Negative results**
- 1. Clopidogrel
- 2. LMWH

**ST segment depression**
- Consistent with unstable angina or NSTEMI
- 1. Clopidogrel
- 2. LMWH

**No high-risk markers**
- No recurrent chest pain
- Provocative stress testing
- Negative results

**Positive results**
- 1. GP IIb/IIIa inhibitor
- 2. Coronary angiography
- 3. Coronary revascularization

**High-risk markers present**
- Elevated troponin
- Persistent/recurrent chest pain
- Persistent ST depression
- Associated heart failure
- Hemodynamic instability
- LVEF <40%
- PCI in preceding 6 months
- Thrombolytic therapy
- Primary PCI

**PredischARGE stress testing**
- Negative results
- Aggressive risk factor modification
- Long-term anti-anginal therapy

**Echocardiogram**
- LMWH: low-molecular-weight heparin; NSTEMI: non-ST-segment elevation myocardial infarction

**Figure 35. Treatment algorithm for chest pain**
Sudden Cardiac Arrest

Definition
• unanticipated, non-traumatic cardiac death in a stable patient which occurs within 1 h of symptom onset; VFib is most common cause

Etiology
• primary cardiac pathology
  ▪ ischemia/MI
  ▪ LV dysfunction
  ▪ severe ventricular hypertrophy
    ▪ HCM
    ▪ AS
  ▪ long QT syndrome
  ▪ congenital heart disease
  ▪ mutations in cardiac ion channels

Management
• acute: resuscitate with prompt CPR and defibrillation
• investigate underlying cause (cardiac catheterization, electrophysiologic studies, echo)
• treat underlying cause
• antiarrhythmic drug therapy: amiodarone, β-blockers
• implantable cardioverter defibrillator (ICD)
• refer to ACLS guidelines (see Anesthesia, A28)

Coronary Revascularization

PERCUTANEOUS CORONARY INTERVENTION (PCI)
• interventional cardiology technique aimed at relieving significant coronary stenosis
• main techniques: balloon angioplasty, stenting
• less common techniques: rotational/directional/extraction atherectomy

Indications
• medically refractory angina
• NSTEMI/UA with high risk features (e.g. high TIMI risk score)
• primary/rescue PCI for STEMI

Balloon Angioplasty and Intracoronary Stenting
• coronary lesions dilated with balloon inflation
• major complication is restenosis (approximately 15% at 6 mo), felt to be due to elastic recoil and neointimal hyperplasia
• majority of patients receive intracoronary stent(s) to prevent restenosis
  ▪ bare metal stent (BMS)
  ▪ drug-eluting stent (DES)
    ▪ coated with antiproliferative drugs (sirolimus, paclitaxel)
    ▪ reduced rate of neointimal hyperplasia and restenosis compared to BMS (5% vs. 20%)
    ▪ complication: late stent thrombosis (5 events per 1000 stents implanted)

Adjunctive Therapies
• ASA and heparin decrease post-procedural complications
• further reduction in ischemic complications has been demonstrated using GPIIb/IIIa inhibitors (abciximab, eptifibatide, tirofiban) in coronary angiography and stenting
• following stent implantation
  ▪ dual antiplatelet therapy (ASA and clopidogrel) for 1 mo with BMS or ≥12 mo with DES
  ▪ ASA and prasugrel can be considered for those at increased risk of stent thrombosis

Procedural Complications
• mortality and emergency bypass rates <1%
• nonfatal MI: approximately 2-3%
CORONARY ARTERY BYPASS GRAFT (CABG) SURGERY

- Objective of CABG is complete reperfusion of the myocardium.

**Indications**

- **CABG**
  - ≥50% diameter stenosis in the left main coronary artery
  - ≥70% diameter stenosis in three major coronary arteries
  - ≥70% diameter stenosis in the proximal LAD artery plus one other major coronary artery
  - Survivors of sudden cardiac arrest with presumed ischemia-mediated VT caused by significant (≥70% diameter) stenosis in a major coronary artery

- **Other:**
  - ≥70% diameter stenosis in two major coronary arteries (without proximal LAD disease) and evidence of extensive ischemia
  - ≥70% diameter stenosis in the proximal LAD artery and evidence of extensive ischemia
  - Multivessel CAD in patients with diabetes
  - LV systolic dysfunction (LVEF 35% to 50%) and significant multivessel CAD or proximal LAD stenosis where viable myocardium is present in the region of intended revascularization

- **PCI**
  - UA/NSTEMI if not a CABG candidate
  - STEMI when PCI can be performed more rapidly and safely than CABG

- **CABG or PCI**
  - One or more significant (≥70% diameter) coronary artery stenosis amenable to revascularization and unacceptable angina despite medical therapy

<tr>
<td>Redo Bypass Grafting</td>
<td></td>
<td>Operative mortality 2-3 times higher than first operation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10% periprocedural MI rate</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reoperation undertaken only in symptomatic patients who failed medical therapy and in whom angiography has documented progression of the disease Increased risk with redo-sternotomy secondary to adhesions which may result in laceration to aorta, RV, IMA/ITA and other bypass grafts</td>
</tr>
</tbody>
</table>

### Operative Issues

- Left ventricular (LV) function is an important determinant of outcome of all heart diseases
- Patients with severe LV dysfunction usually have poor prognosis, but surgery can sometimes dramatically improve LV function
- Assess viability of non-functioning myocardial segments in patients with significant LV dysfunction using delayed thallium myocardial imaging, PET scanning or MRI.

</tr>
<tr>
<td></td>
<td>Cerebrovascular disease</td>
</tr>
</tbody>
</table>

**Procedural Complications**
- CABG using cardiopulmonary bypass (CPB)
  - stroke and neurocognitive defects (microembolization of gaseous and particulate matter)
  - immunosuppression
  - systemic inflammatory response leading to:
    - myocardial dysfunction
    - renal dysfunction
    - neurological injury
    - respiratory dysfunction
    - coagulopathies

**OFF-PUMP CORONARY ARTERY BYPASS (OPCAB) SURGERY**

**Procedure**
- OPCAB avoids the use of CPB by allowing surgeons to operate on a beating heart
  - stabilization devices (e.g. Genzyme Immobilizer®) hold heart in place allowing operation while positioning devices (Medtronic Octopus® and Starfish® system) allow the surgeon to lift the beating heart to access the lateral and posterior vessels
  - procedure is safe and well tolerated by most patients; however, OPCAB surgery remains technically more demanding

**Indications**
- used in poor candidates for CPB who have: calcified aorta, poor LVEF, severe peripheral vascular disease (PVD), severe COPD, chronic renal failure, coagulopathy, transfusion objections (e.g. Jehovah’s Witness), good target vessels, anterior/lateral wall revascularization, target revascularization in older, sicker patients
- **absolute contraindications**: hemodynamic instability, poor quality target vessels including intramyocardial vessels, diffusely diseased vessels and calcified coronary vessels
- **relative contraindications**: cardiomegaly/CHF, critical left main disease, small distal targets, recent or current acute MI, cardiogenic shock, LVEF <35%

**Outcomes**
- OPCAB decreases in-hospital morbidity (decreased incidence of chest infection, inotropic requirement, supraventricular arrhythmia), blood product transfusion, ICU stay, length of hospitalization, and CK-MB and troponin I levels
- no significant difference in terms of survival at 2 yr, frequency of cardiac events (MI, PCI, CHF, recurrent angina, redo CABG) or medication usage compared to on-pump CABG

**Heart Failure**

### Congestive Heart Failure (CHF)

**Definitions**
- heart failure: a complex clinical syndrome, resulting from almost any cardiac disorder that impairs the ability of the ventricle to fill with or eject blood
- forward heart failure: heart unable to maintain adequate cardiac output to meet demand or is able to do so only by elevating filling pressure
- backward heart failure: heart unable to accommodate venous return resulting in elevated filling pressures and vascular congestion (systemic or pulmonary)
- heart failure can involve left side of heart (left heart failure), right side (right heart failure) or both (biventricular failure) (see Table 11)
- heart failure can also have components of ineffective ventricular filling (diastolic dysfunction) and/or contraction (systolic dysfunction)
- most cases associated with poor cardiac output (low-output heart failure); however, some cases of CHF not due to intrinsic cardiac disease but instead due to increased demand (high-output heart failure)
Pathophysiology

- primary insults (myocyte loss, overload) → pump dysfunction, which leads to:
  - remodeling (dilatation, hypertrophy)
  - neurohumoral activation → necrosis and apoptosis
- both pathways result in further damage (re-starting the cycle), edema, tachycardia, vasoconstriction, congestion
- compensatory response to myocardial stress (perpetuate disease process)
  - increased end-systolic ventricular pressure (pressure overload)
    - e.g. HTN, aortic stenosis → hypertrophy
  - increased end-diastolic ventricular volume (volume overload)
    - e.g. aortic regurgitation → cardiac dilatation
- systemic response to ineffective circulating volume
  - activation of sympathetic nervous and renin-angiotensin-aldosterone systems results in:
    - salt and water retention with intravascular expansion
    - increased heart rate and myocardial contractility
    - increased afterload

Systolic Dysfunction

- impaired myocardial contractile function → decreased LVEF and SV → decreased CO
- findings: apex beat displaced, S3, increased heart size on CXR, decreased LVEF, LV dilatation
- causes:
  - ischemic (e.g. extensive CAD, previous MI)
  - non-ischemic
    - HTN
    - DM
    - alcohol (and other toxins)
    - myocarditis
  - dilated cardiomyopathy (multiple causes – see Dilated Cardiomyopathy, C36)

Heart Failure with Preserved Ejection Fraction (HFPEF)

- previously known as “diastolic dysfunction”
- up to 1/2 of all HF patients have normal systolic function (i.e. normal ejection fraction) and the cause of heart failure is impaired diastolic filling: prevalence higher in older patients
- increased LV filling pressures produce venous congestion upstream (i.e. pulmonary and systemic venous congestion)
- findings: HTN, apex beat sustained, S4, normal-sized heart on CXR, LVH on ECG/echo, normal LVEF
- causes of decreased compliance:
  - transient: ischemia (relaxation of myocardium is active and requires ATP)
  - permanent
    - severe hypertrophy (HTN, aortic stenosis, HCM)
    - restrictive cardiomyopathy (e.g. amyloid)
    - MI

High-Output Heart Failure

- caused by demand for increased cardiac output
- often exacerbates existing heart failure or decompensates a patient with other cardiac pathology
- differential diagnosis: anemia, thiamine deficiency (beriberi), hyperthyroidism, A-V fistula or L-R shunting, Paget's disease, renal disease, hepatic disease

---

**Table 11. Signs and Symptoms of Left vs. Right Heart Failure**

<table>
<thead>
<tr>
<th>Left Failure</th>

**Dichotomies of Heart Failure**

- Forward vs. Backward
- Left-sided vs. Right-sided
- Systolic vs. Diastolic dysfunction
- Low output vs. High output

**Use Ejection Fraction to Grade LV Dysfunction**

- Grade I (EF > 60%) (Normal)
- Grade II (EF = 40-59%)
- Grade III (EF = 21-39%)
- Grade IV (EF < 20%)

**A Validated Clinical and Biochemical Score for the Diagnosis of Acute Heart Failure: the ProBNP Investigation of Dyspnea in the Emergency Department (PRIDE) Acute Heart Failure Score**

Likelihood of heart failure:

- Law = 0.6
- Intermediate = 6-8
- High = 9-14

---

**New York Heart Association (NYHA) Functional Classification of Heart Failure**

- Class I: ordinary physical activity does not cause symptoms of HF
- Class II: comfortable at rest, ordinary physical activity results in symptoms
- Class III: marked limitation of ordinary activity; less than ordinary physical activity results in symptoms
- Class IV: inability to carry out any physical activity without discomfort; symptoms may be present at rest

---

**Brain natriuretic peptide (BNP) is secreted by ventricles due to LV stretch and wall tension. Cardiomyocytes secrete BNP precursor that is cleaved into proBNP. After secretion into ventricles, proBNP is cleaved into the active C-terminal portion and the inactive NT-proBNP. The above scoring algorithm developed by Bagga et al. is commonly used. A score of <5 has a negative predictive value of 86%, while scores >8 had a sensitivity of 96% and specificity of 84% (P < 0.001) for the diagnosis of acute heart failure.**
Etiologies of Primary Insults
- consider predisposing, precipitating and perpetuating factors

Precipitants of Symptomatic Exacerbations
- consider natural progression of disease vs. new precipitant
- always search for reversible cause
- differential diagnosis can also be organized as follows:
  - new cardiac insult/disease: MI, arrhythmia, valvular disease
  - new demand on CV system: HTN, anemia, thyrotoxicosis, infection, etc.
- failure to take medications as prescribed

Investigations
- identify and assess precipitating factors and treatable causes of CHF
- blood work: CBC, electrolytes (including calcium and magnesium), BUN, creatinine, fasting blood glucose, Hba1c, lipid profile, liver function tests, serum TSH, ± ferritin, BNP, uric acid
- ECG: look for chamber enlargement, arrhythmia, ischemia/infarction
- CXR: cardiomegaly, pleural effusion, redistribution, Kerley B lines, bronchiolar-alveolar cuffing
- echo: LV EF, cardiac dimensions, wall motion abnormalities, valvular disease, pericardial effusion
- radionuclide angiography: LV EF
- myocardial perfusion scintigraphy (thallium or sestamibi SPECT)

Acute Treatment of Pulmonary Edema
- treat acute precipitating factors (e.g. ischemia, arrhythmias)
- L – Lasix® (furosemide) 40-500 mg IV
- M – morphine 2-4 mg IV: decreases anxiety and preload (venodilation)
- N – nitroglycerin: topical/IV/SL
- O – oxygen: in hypoxemic patients
- P – positive airway pressure (CPAP/BiPAP): decreases preload and need for ventilation when appropriate
- P – position: sit patient up with legs hanging down unless patient is hypotensive

in ICU setting or failure of LMNOPP, other interventions may be necessary
- nitroprusside IV
- hydralazine PO
- sympathomimetics
  - dopamine
    - low dose: selective renal vasodilation (high potency D1 agonist)
    - medium dose: inotropic support (medium potency β1 agonist)
    - high dose: increases SVR (low potency β1 agonist), which is undesirable
  - dobutamine
    - selective inotrope (β1 agonist) and arterial vasodilator (β1 antagonist)
  - phosphodiesterase inhibitors (milrinone)
    - inotropic effect and vascular smooth muscle relaxation (decreased SVR), similar to dobutamine
- consider pulmonary artery catheter to monitor pulmonary capillary wedge pressure (PCWP)
  - if patient is unstable or a cardiac etiology is uncertain (PCWP >18 indicates likely cardiac etiology)
- mechanical ventilation as needed
- rarely used, but potentially life-saving measures:
  - intra-aortic balloon pump (IABP)
  - left or right ventricular assist device (LVAD/RVAD)
  - cardiac transplant

Long Term Management
- note that most evidence-based management applies to HFREF
- priorities in HFPEF focus on controlling systolic and diastolic hypertension, as a risk factor
- control measure
- priorities in HFREF focus on controlling systolic and diastolic hypertension, as a risk factor
- control measure

Conservative Measures
- symptomatic measures: oxygen in hospital, bedrest, elevate the head of bed
- lifestyle measures: diet, exercise, DM control, smoking cessation, decrease alcohol consumption, patient education, sodium and fluid restriction
- multidisciplinary heart failure clinics: for management of individuals at higher risk, or with recent hospitalization

Toronto Notes 2014

Five Most Common Causes of CHF
- CAD (60-70%)
- HTN
- Idiopathic (often dilated cardiomyopathy)
- Valvular (e.g. AS, AR and MR)
- Alcohol (dilated cardiomyopathy)

Precipitants of Heart Failure
HEART FAILED
Hypertension (common)
Endocarditis/environment (e.g. heat wave)
Anemia
Rheumatic heart disease and other valvular disease
Thyrotoxicosis
Failure to take meds (very common)
Arrhythmia (common)
Infection/Ischemia/Infarction (common)
Lung problems (PE, pneumonia, COPD)
Endocrine (pheochromocytoma, hyperaldosteronism)
Diabetic indiscritions (common)

Various clinical guidelines, including the Acute Heart Failure Syndromes AHA 2010 Guidelines, and the 2012 Canadian Cardiovascular Society (CCS) Heart Failure Management Guidelines, indicate the current approach of acute heart failure exacerbation may be too homogenous. The CCS guidelines in particular offer several suggestions, including cautious use of oxygen in normoxic patients due to the possible risk of causing increased systemic resistance and reduced cardiac output, reserving the use of non-invasive ventilation for patients not responding to medical therapy, as well as preference for high dose rather than low dose diuretic therapy.

The most common cause of right heart failure is left heart failure.

Measuring NT-pro BNP
BNP is secreted by ventricles due to LV stretch and wall tension.
Cardiomyocytes secrete BNP precursor that is cleaved into proBNP. After secretion into ventricles proBNP is cleaved into the active C-terminal portion and the inactive NT-proBNP portion.

Limitations: Age, body habitus, renal function, pulmonary embolism
Pharmacological Therapy

1. Vasodilators
   - ACEI: standard of care – slows progression of LV dysfunction and improves survival
     - all symptomatic patients functional class II-IV
     - all asymptomatic patients with LVEF <40%
   - post-MI
   - angiotensin II receptor blockers (ARBs)
     - second-line to ACEI if not tolerated, or as adjunct to ACEI if β-blockers not tolerated
     - – hydralazine and nitrates
     - second-line to ACEI, decrease in mortality not as great as with ACEI
   - may consider in acute renal failure until creatinine stabilizes

2. β-blockers: slow progression and improve survival
   - class I-III with LVEF <40%
   - stable class IV patients
   - note: should be used cautiously, titrate slowly because may initially worsen CHF

3. Diuretics: symptom control, management of fluid overload
   - furosemide (40-500 mg daily) for potent diuresis
   - metolazone may be used with furosemide to increase diuresis
   - furosemide, metolazone, and thiazides oppose the hyperkalemia that can be induced by
     β-blockers, ACEI, ARBs, and aldosterone antagonists

4. Aldosterone antagonists: mortality benefit in severe CHF
   - spironolactone for class IIB and IV CHF already on ACEI and loop diuretic
   - eplerenone may be considered if intolerable endocrine side effects
   - note: potential for life threatening hyperkalemia
     - monitor K⁺ after initiation and avoid if Cr >220 μmol/L or K⁺ >5.2 mmol/L

5. Inotropes: digoxin improves symptoms and decreases hospitalizations, no effect on mortality
   - indications: patient in sinus rhythm and symptomatic on ACEI, or CHF and AFib
   - patients on digitalis glycosides may worsen if these are withdrawn

6. Antiarrhythmic drugs: for use in CHF with arrhythmia
   - can use amiodarone, β-blocker, or digoxin

7. Anticoagulants: warfarin for prevention of thromboembolic events
   - prior thromboembolic event or AFib, presence of LV thrombus on echo
   - possible benefit in other patients with LVEF <30% (controversial)

Procedural Interventions

- resynchronization therapy: symptomatic improvement with biventricular pacemaker
  - consider if QRS >130 msec, LVEF <35%, and severe symptoms despite optimal therapy
  - greatest benefit likely with marked LV enlargement, mitral regurgitation, QRS >150 msec,
    high diuretic requirement
- ICD: mortality benefit in 1st prevention of sudden cardiac death
  - prior MI, optimal medical therapy, LVEF <30%, clinically stable
  - prior MI, non-sustained VT, LVEF 30-40%, EPS inducible VT
- LVAD/RVAD (see Ventricular Assist Devices, C34)
- cardiac transplantation (see Cardiac Transplantation, C34)
- valve repair if patient is surgical candidate and has significant valve disease contributing to CHF
  (see Valvular Heart Disease, C38)
Sleep-Disordered Breathing

- 45-55% of patients with CHF have sleep disturbances, including Cheyne-Stokes breathing and sleep apnea (central or obstructive)
- associated with a worse prognosis and greater LV dysfunction
- nasal continuous positive airway pressure (CPAP) is effective in treating Cheyne-Stokes respiration/sleep apnea with improvement in cardiac function and symptoms

Cardiac Transplantation

- treatment for end-stage heart disease; due to ischemic or non-ischemic cardiomyopathy
- worldwide 1-yr survival is 85-90%, 5-yr survival about 60%, annual mortality rate of 4%
- matching is according to blood type, body size and weight (should be within 25%), and HLA tissue matching (if time allows)

Indications for Surgery

- severe cardiac disability despite maximal medical therapy (recurrent hospitalizations for CHF, NYHA III or IV, peak metabolic oxygen consumption <14 mL/kg/min in absence of β-blocker)
- symptomatic cardiac ischemia refractory to conventional treatment (unstable angina not amenable to CABG or angioplasty with LVEF <30%; recurrent, symptomatic ventricular arrhythmias)
- exclusion of all surgical alternatives to cardiac transplantation

Prerequisites

- emotionally stable with social support
- medically compliant and motivated
- relative contraindications: incurable malignancy, major systemic illness, irreversible major organ disease (e.g. renal, hepatic), active systemic infection (e.g. Hep C, HIV), obesity, irreversible pulmonary HTN (pulmonary vascular resistance [PVR] >6 Wood units), severe COPD (FEV1 ≤1 L) or active drug addiction or alcoholism

Complications

- rejection
  - common, less than 5% have serious hemodynamic compromise
  - gold standard to detect rejection: endomyocardial biopsy
  - no noninvasive tests to detect rejection
- infection
  - leading cause of morbidity and mortality after cardiac transplantation
- allograft CAD
  - approximately 50% develop graft CAD within 5 yr of transplantation
  - most common cause of late death following transplantation
- malignancy
  - develops in 15% of cardiac transplant recipients due to immunosuppressive medication
  - second most common cause of late death following transplantation
- cutaneous neoplasms most common, followed by non-Hodgkin’s lymphoma and lung cancer
- immunosuppressive medication side effects (prednisone, cyclosporine, tacrolimus, sirolimus)

Ventricular Assist Devices (VADs)

- work to unload the ventricle while maintaining output; also results in decreased myocardial oxygen consumption permitting recovery of the myocardium that is not irreversibly injured
- can support the left (LVAD), right (RVAD), or both ventricles (BiVAD)
- indications
  - bridge to transplantation
  - postoperative mechanical support when unable to separate from cardiopulmonary bypass despite inotropic and intra-aortic balloon pump (IABP) support
  - IABP is a catheter based device inserted into the aorta via the femoral artery that decreases myocardial O2 demand and increases blood flow to coronary arteries
  - postoperative cardiogenic shock

Influence of Ejection Fraction on Cardiovascular Outcomes in a Broad Spectrum of Heart Failure Patients

Methods: 7599 patients from the CHARM study (Candesartan in Heart failure: Assessment of Reduction in Mortality and morbidity; RCT comparing placebo vs. candesartan in patients with NYHA class II to IV). Compared LVEF to cardiovascular outcomes and causes of death.

Results: All-cause mortality increased by 39% per 10% reduction in LVEF below 45% (Hazard ratio 1.39, 95%CI 1.32-1.46). For LVEF>45%, ejection fraction does not further contribute to assessment of cardiovascular risk in HF patients.

Conclusions: At LVEF<45%, lower ejection fractions were associated with poorer cardiovascular outcomes.

Higher New York Heart Association Classes and Increased Mortality and Hospitalization in Patients with Heart Failure and Preserved Left Ventricular Function

Methods: Retrospective follow-up study (median 30.5 mo) of 988 patients with heart failure with ejection fraction >45%. Estimated risks of various outcomes using Cox proportional hazard models.

Results: Adjusted hazard ratio for all-cause mortality for NYHA class II, III, IV patients was 1.54, 2.16, and 0.46, respectively. Adjusted hazard ratio for all-cause hospitalization for NYHA class II, III, IV patients was 1.33, 1.71, and 2.4, respectively.

Conclusions: Higher NYHA classes were associated with poorer outcomes in patients with heart failure and preserved systolic function.

Effects of Donor Pre-treatment with Dopamine on Survival After Heart Transplantation: A Cohort Study of Heart Transplant Recipients Nested in a Randomized Controlled Multicenter Trial

Purpose: To establish the association between NYHA class and outcomes with heart failure and preserved systolic function.

Methods: Retrospective follow-up study (median 38.5 mo) of 988 patients with heart failure.

Results: Adjusted hazard ratio for all-cause mortality >45%. Risk peaks early during the first few months after transplantation and then declines to a low persistence rate.

Conclusions: Higher NYHA classes were associated with poorer outcomes in patients with heart failure and preserved systolic function.
Myocardial Disease

Definition of Cardiomyopathy
- intrinsic or primary myocardial disease not secondary to congenital, hypertensive, coronary, valvular, or pericardial disease
- functional classification: dilated, hypertrophic, or restrictive
- LV dysfunction 2º to MI often termed “ischemic cardiomyopathy”, is not a true cardiomyopathy (i.e. primary myocardial disorder) since the primary pathology is obstructive CAD

Table 12. Summary Table for CHF and Myocardial Disease

Myocarditis

Definition
- inflammatory process involving the myocardium ranging from acute to chronic; an important cause of dilated cardiomyopathy

Etiology
- idiopathic
- infectious
  - viral: S. aureus, C. perfringens, C. diphtheriae, Mycoplasma, Rickettsia
  - fungi
  - spirochetal (Lyme disease – Borrelia burgdorferi)
  - Chagas disease (Trypanosoma cruzi), toxoplasmosis
- toxic: catecholamines, chemotherapy, cocaine
- hypersensitivity/eosinophilic: drugs (antibiotics, diuretics, lithium, clozapine), insect/snake bites
- systemic diseases: collagen vascular diseases (SLE, RA, others), sarcoidosis, autoimmune
- other: giant cell myocarditis, acute rheumatic fever

Signs and Symptoms
- constitutional symptoms
- acute CHF
- chest pain – due to pericarditis or cardiac ischemia
- arrhythmias
- systemic or pulmonary emboli
- sudden death

Investigations
- ECG: non-specific ST-T changes ± conduction defects
- bloodwork
  - increased CK, troponin, LDH, and AST with acute myocardial necrosis ± increased WBC, ESR, ANA, rheumatoid factor, complement levels
  - blood culture, viral titres and cold agglutinins for Mycoplasma
- CXR: enlarged cardiac silhouette
- echo: dilated, hypokinetic chambers, segmental wall motion abnormalities
- myocardial biopsy

Management
- supportive care
- restrict physical activity
- treat CHF
- treat arrhythmias
- anticoagulation
- treat underlying cause if possible

Prognosis
- usually self-limited and often unrecognized, many recover
- sudden death in young adults
- may progress to dilated cardiomyopathy
Dilated Cardiomyopathy (DCM)

Definition
- unexplained dilation and impaired systolic function of one or both ventricles

Etiology
- idiopathic (presumed viral or idiopathic) ~50% of DCM
- alcohol
- familial/genetic
- uncontrolled tachycardia (e.g. persistent rapid AFib)
- collagen vascular disease: SLE, polyarteritis nodosa, dermatomyositis, progressive systemic sclerosis
- infectious: viral (coxsackie B, HIV), Chagas disease, Lyme disease, Rickettsial diseases, acute rheumatic fever, toxoplasmosis
- neuromuscular disease: Duchenne muscular dystrophy, myotonic dystrophy, Friedreich's ataxia
- metabolic: uremia, nutritional deficiency (thiamine, selenium, carnitine)
- endocrine: hyper/hypothyroidism, DM, pheochromocytoma
- peripartum
- toxic: cocaine, heroin, organic solvents
- drugs: chemotherapies (doxorubicin, cyclophosphamide), antiretrovirals, chloroquine, clozapine, TCA
- radiation

Signs and Symptoms
- may present as:
  - CHF
  - systemic or pulmonary emboli
  - arrhythmias
  - sudden death (major cause of mortality due to fatal arrhythmia)

Investigations
- bloodwork: CBC, electrolytes, Cr, bicarbonate, BNP, CK, troponin, LFTs, TSH, TIBC
- ECG: variable ST-T wave abnormalities, poor R wave progression, conduction defects (e.g. BBB), arrhythmias (non-sustained VT)
- CXR: global cardiomegaly (globular heart), signs of CHF, pleural effusion
- echo: chamber enlargement, global hypokinesis, depressed LVEF, MR and TR, mural thrombi
- endomyocardial biopsy: not routine, used to rule out a treatable cause
- coronary angiography: in selected patients to exclude ischemic heart disease

Management
- treat underlying disease: e.g. abstinence from alcohol
- treat CHF: see Heart Failure, C30
- thromboembolism prophylaxis: anticoagulation with warfarin
- indicated for: AFib, history of thromboembolism or documented thrombus
- LVEF <30% (controversial)
- treat symptomatic or serious arrhythmias
- immunize against influenza and S. pneumoniae
- consider surgical options (e.g. LVAD, transplant, volume reduction surgery) in appropriate candidates with severe, drug refractory disease
- consider ICD among patients with a LVEF <30%

Prognosis
- depends on etiology
- better with reversible underlying cause, worst with infiltrative diseases, HIV, drug-induced
- cause of death usually CHF (due to pump failure) or sudden death 2nd to ventricular arrhythmias
- systemic emboli are significant source of morbidity
- 20% mortality in 1st yr, 10% per year after

Hypertrophic Cardiomyopathy (HCM)

- see 2011 ACCF/AHA Guideline for the Diagnosis and Treatment of Hypertrophic Cardiomyopathy for details

Definition
- defined as unexplained ventricular hypertrophy
- various patterns of HCM are classified, but most causes involve pattern of septal hypertrophy

Etiology and Pathophysiology
- histopathologic features include myocyte disarray, myocyte hypertrophy, and interstitial fibrosis
- cause is felt to be a genetic defect involving one of the cardiac sarcomeric proteins (>400 mutations associated with autosomal dominant inheritance, incomplete penetrance)
- prevalence of 1/500-1/1000 in general population
- generally presents in early adulthood
Hemodynamic Classification
- hypertrophic obstructive cardiomyopathy (HOCM): dynamic LV outflow tract (LVOT) obstruction, either at rest or with provocation, defined as LVOT gradient of at least 30 mmHg
- non-obstructive HCM: no LVOT obstruction
- many patients have diastolic dysfunction (impaired ventricular filling secondary to LV hypertrophy which decreases compliance)

Signs and Symptoms
- clinical manifestations: asymptomatic (common, therefore screening is important), SOB on exertion, angina, presyncope/syncope (due to LV outflow obstruction or arrhythmia), CHF, arrhythmias, SCD
- pulses: rapid upstroke, "spike and dome" pattern in carotid pulse (in HCM with outflow tract obstruction)
- precordial palpation: PMI localized, sustained, double impulse, ‘triple ripple’ (triple apical impulse in HOCM), LV lift
- precordial auscultation: normal or paradoxically split S2, S4, harsh systolic diamond-shaped murmur at LLSB or apex, enhanced by squat to standing or Valsalva (murmur secondary to LVOT obstruction as compared to AS); often with pansystolic murmur due to mitral regurgitation

Investigations
- ECG/Holter monitor: LVH, high voltages across precordium, prominent Q waves (lead I, aVL, V5, V6), tall R wave in V1, P wave abnormalities
- transthoracic echocardiography and echo-Doppler study: asymmetric septal hypertrophy (less commonly apical), systolic anterior motion (SAM) of mitral valve and MR; LVOT gradient can be estimated by Doppler measurement
- genetic cardiac resonance magnetic resonance imaging indicated when echocardiography is inconclusive for diagnosis
- cardiac catheterization (only when patient being considered for invasive therapy)

Management
- avoid factors which increase obstruction (e.g. volume depletion)
- avoidance of all competitive sports
- treatment of obstructive HCM
  - medical agents: β-blockers, verapamil, phenylephrine, disopyramide
  - avoid nitrates, diuretics and ACEI as they increase LVOT gradient and worsen symptoms
- patients with drug-refractory symptoms
  - surgical myectomy
  - ICD placement
  - septal ethanol ablation
  - dual chamber pacing (rarely done)
- treatment of ventricular arrhythmias: amiodarone or ICD
- first-degree relatives of patients with HCM should be screened annually during adolescence (physical, ECG, 2D echo), then serially every 5 yr during adulthood
- first-degree genetic testing and family screening
- screening for sudden cardiac death: VF, VT, family history, unexplained syncope, maximal LV wall thickness ≥30 mm

Prognosis
- potential complications: AFib, VT, CHF, sudden cardiac death (1% risk/yr; most common cause of SCD in young athletes)
  - major risk factors for sudden death (consider ICD placement)
  - history of survived cardiac arrest/sustained VT
  - family history of multiple premature sudden deaths
  - other factors associated with increased risk of sudden cardiac death
  - syncope (presumed to be arrhythmic in origin)
  - non-sustained VT on ambulatory monitoring
  - marked ventricular hypertrophy (maximum wall thickness ≥30 mm)
  - abnormal BP in response to exercise (in patients <40 yr old with HCM)

Restrictive Cardiomyopathy (RCM)

Definition
- impaired ventricular filling with preserved systolic function in a non-dilated, non-hypertrophied ventricle secondary to factors that decrease myocardial compliance (fibrosis and/or infiltration)

Etiology
- infiltrative: amyloidosis, sarcoidosis
- non-infiltrative: scleroderma, idiopathic myocardial fibrosis
- storage diseases: hemochromatosis, Fabry’s disease, Gaucher’s disease, glycogen storage diseases
- endomyocardial
  - endomyocardial fibrosis, Loeffler’s endocarditis or eosinophilic endomyocardial disease
  - radiation heart disease
- carcinoid syndrome (may have associated tricuspid valve or pulmonary valve dysfunction)

RCM vs. Constrictive Pericarditis (CP)
- Present similarly but CP is treatable with surgery.
Clinical Manifestations
• CHF (usually with preserved LV systolic function), arrhythmias
• elevated JVP with prominent x and y descents, Kussmaul’s sign
• S3, S4, MR, TR
• thromboembolic events

Investigations
• ECG: low voltage, non-specific, diffuse ST-T wave changes ± non-ischemic Q waves
• CXR: mild cardiac enlargement
• echo: LAE, RAE; specific Doppler findings with no significant respiratory variation
• cardiac catheterization: increased end-diastolic ventricular pressures
• endomyocardial biopsy: to determine etiology (especially for infiltrative RCM)

Management
• exclude constrictive pericarditis
• treat underlying disease: control HR, anticoagulate if AFib
• supportive care and treatment for CHF, arrhythmias
• heart transplant: might be considered for CHF refractory to medical therapy

Prognosis
• depends on etiology

Valvular Heart Disease

Infective Endocarditis (IE)

• see Infectious Diseases, ID17
• American Heart Association (AHA) 2007 guidelines recommend IE prophylaxis
  • only for patients with:
    • prosthetic valve material
    • past history of IE
    • certain types of congenital heart disease
    • cardiac transplant recipients who develop valvulopathy
  • only for the following procedures:
    • dental
    • respiratory tract
    • procedures on infected skin/skin structures/MSK structures
    • not GI/GU procedures specifically

Rheumatic Fever

• see Pediatrics, P61

Prognosis
• acute complications: myocardiitis (DCM/CHF), conduction abnormalities (sinus tachycardia, AFib), valvulitis (acute MR), acute pericarditis (not constrictive pericarditis)
• chronic complications: rheumatic valvular heart disease – fibrous thickening, adhesion, calcification of valve leaflets resulting in stenosis/regurgitation, increased risk of IE ± thromboembolism
• onset of symptoms usually after 10-20-yr latency from acute carditis of rheumatic fever
• mitral valve most commonly affected

Choice of Valve Prosthesis

A Bedside Clinical Prediction Rule for Detecting Moderate or Severe Aortic Stenosis

Study Design: Blinded cross sectional study with 124 patients of an ambulatory cardiology clinic. Patients were examined for: 1) murmur over the right clavicle 2) murmur loudest at second right intercostal space 3) reduced intensity of S2 4) reduced volume of the carotid pulse 5) delayed carotid upstroke.

Methods: Patients were examined by blinded investigators and the clinical examination findings were compared to findings on subsequent echocardiography. Moderate to severe aortic stenosis was defined as a valve area < 1.2 cm² or a peak intensity gradient of > 2.5 mHg.

Results: Absence of a murmur over the right clavicle ruled out aortic stenosis while presence of ≥ 3 of the 4 associated symptoms ruled in aortic stenosis (LR = 40).

Conclusions: Bedside techniques can accurately rule in and rule out moderate to severe aortic stenosis.
## Summary of Valvular Disease

### Table 14. Valvular Heart Disease

- **Aortic Stenosis (AS)**
- **Mitral Stenosis (MS)**
- **Aortic Regurgitation (AR)**
- **Mitral Regurgitation (MR)**

### Aortic Stenosis (AS)
- **Etiology**
  - Congenital (bicuspid, unicuspid valve), calcification (wear and tear), rheumatic disease
- **Definition**
  - Normal aortic valve area = 3-4 cm²
- **Pathophysiology**
  - MS → fixed CO and LAE → increased LA pressure → pulmonary vascular resistance and CHF, worse with Afib (no atrial kick), tachycardia (decreased atrial emptying time) and pregnancy (increased preload)
- **Symptoms**
  - Exertional angina, syncope, dyspnea, PND, orthopnea, peripheral edema
- **Physical Exam**
  - Narrow pulse pressure, brachial-radial delay, pulsus parvus et tardus, sustained PMI
- **Investigations**
  - ECG: LVH and strain, LBBB, LAE, AFib
  - CXR: LVH, LAE, aortic root dilatation
  - Echo: reduced valve area, pressure gradient, LVH, reduced LV function
- **Treatment**
  - Asymptomatic: serial echos, avoid exertion
  - Symptomatic: avoid nitrates/arterial dilators and ACEI in severe AS
- **Surgical Options**
  - Valve replacement: aortic valve replacement and trileaflet valve
  - Prior to pregnancy (if AS significant) and CHF; worse with AFib (no atrial kick), tachycardia (decreased atrial emptying time)
- **Interventional Options**
  - Percutaneous valve replacement (transfemoral or transapical approach) is an option in selected patients who are not considered good candidates for surgery

### Mitral Stenosis (MS)
- **Etiology**
  - Rheumatic disease most common cause, congenital (rare)
- **Definition**
  - Severe MS is mitral valve area (MVA) < 1.2 cm²
- **Pathophysiology**
  - MS → fixed CO and LAE → increased LA pressure → pulmonary vascular resistance and CHF, worse with Afib (no atrial kick), tachycardia (decreased atrial emptying time) and pregnancy (increased preload)
- **Symptoms**
  - SOB on exertion, orthopnea, fatigue, palpitations, peripheral edema, malar flush, pinched and blue facies (severe MS)
- **Physical Exam**
  - AFib, no "a" wave on JVP, left parasternal lift, displaced hyperdynamic apex, left parasternal lift, apical thrill
- **Investigations**
  - ECG: NSR/Afib, LAE (P mitrale), RVH, RAD
  - CXR: LVH, LAE, CHF, mitral valve calcification
- **Treatment**
  - Avoid exertion, fever (increased LA pressure), treat Afib and CHF, increase diastolic filling time (β-blockers, digitalis)
  - Surgery if: NYHA class III-IV CHF and failure of medical therapy

### Aortic Regurgitation (AR)
- **Etiology**
  - Supravalvular: aortic root disease (Marfan’s, atherosclerosis and dissecting aneurysm, connective tissue disease)
- **Definition**
  - Valve: congenital (bicuspid aortic valve, large VSD), IE
- **Pathophysiology**
  - Volume overload → LV dilatation → increased SV, high SBP and low dBP → increased wall tension → pressure overload → LVH (low dBP → decreased coronary perfusion)
- **Symptoms**
  - Usually only becomes symptomatic late in disease when LV failure develops
- **Physical Exam**
  - Waterhammer pulse, bisferiens pulse, femoral-brachial SBP > 20 (Hill’s test wide pulse pressure), hyperdynamic apex, displaced PMI, heaving apex
- **Investigations**
  - ECG: LVH, LAE, Aortic root dilatation
  - CXR: LVH, LAE, aortic root dilatation
- **Treatment**
  - Asymptomatic: serial echos, afterload reduction (e.g. ACEI, nifedipine, hydralazine)
  - Symptomatic: avoid exertion, treat CHF
  - Surgery if: NYHA class III-IV CHF; LV dilatation and/or LVEF <50% with/without symptoms
- **Surgical Options**
  - Valve replacement: most patients
  - Valve repair: very limited role
  - Aortic root replacement (Bentall procedure): when ascending aortic aneurysm present, valvular conduit used

### Mitral Regurgitation (MR)
- **Etiology**
  - Mitral valve prolapse, congenital cleft leaflets, LV dilatation/aneurysm (CHF, DCM, myxomatosis), IE abscess, Marfan’s syndrome, HOCM, acute MI, myxoma, mitral valve annulus calcification, chordae/papillary muscle trauma/trauma/ischemia/rupture (acute), rheumatic disease
- **Pathophysiology**
  - Reduced CO → increased LV and LA pressure → LV and LA dilatation → CHF and pulmonary HTN
- **Symptoms**
  - Dyspnea, PND, orthopnea, palpitations, peripheral edema
- **Physical Exam**
  - Displaced hyperdynamic apex, left parasternal lift, apical thrill
- **Investigations**
  - ECG: LAE, LVH, pulmonary venous HTN
  - CXR: LVH, LAE, pulmonary venous HTN
- **Treatment**
  - Asymptomatic: serial echos
  - Symptomatic: decrease preload (diuretics), decrease afterload (ACEI) for severe MR and poor surgical candidates; stabilize acute MR with vasodilators before surgery
  - Surgery if: acute MR with CHF, papillary muscle rupture, NYHA class III-IV CHF, AF; increasing LV size or worsening LV function, earlier surgery if valve repairable (>90% likelihood) and patient is low-risk for surgery
  - Surgical Options
  - Valve repair: >75% of pts with MR and myxomatous mitral valve prolapse – annuloplasty rings, leaflet repair, chordae transfers/shorten/replacement
  - Valve replacement: failure of repair, heavily calcified annulus
  - Advantage of repair: low rate of endocarditis, no anticoagulation, less chance of re-operation
Table 14. Valvular Heart Disease (continued)

### Tricuspid Stenosis (TS)

**Etiology**
Rheumatic disease, congenital, carcinoid syndrome, fibroelastosis; usually accompanied by MS

**Pathophysiology**
Increased RA pressure → right heart failure → decreased CO and fixed on exertion

**Symptoms**
Peripheral edema, fatigue, palpitations

**Physical Exam**
Prominent "s" waves in JVP, +ve abdominojugular reflex, Kussmaul’s sign, diastolic rumble 4th left intercostal space

**Investigations**
ECG: normal, RAE, RVH
CXR: prominent pulmonary arteries if pulmonary HTN; enlarged RV

**Treatment**
Preload reduction (diuretics), slow HR
Surgery if: only if other surgery required (e.g. mitral valve replacement)

**Surgical Options**
- Valve Replacement:
  - if severely diseased valve
  - bioprosthesis preferred

### Pulmonary Stenosis (PS)

**Etiology**
Usually congenital, rheumatic disease (rare), carcinoid syndrome

**Pathophysiology**
Increased RV pressure → RV hypertrophy → right heart failure

**Symptoms**
Chest pain, syncope, fatigue, peripheral edema

**Physical Exam**
Systolic murmur at 2nd left intercostal space accentuated by inspiration, pulmonary ejection click, right-sided S4

**Investigations**
ECG: RVH
CXR: prominent pulmonary arteries enlarged RV
Echo: diagnostic

**Treatment**
Balloon valvuloplasty if severe symptoms

**Surgical Options**
Percutaneous or open balloon valvuloplasty

### Tricuspid Regurgitation (TR)

**Etiology**
RV dilatation, IE (partially due to IV drug use), rheumatic disease, congenital (Ebstein anomaly), carcinoid

**Pathophysiology**
RV dilatation → TR → further RV dilatation → right heart failure

**Symptoms**
Peripheral edema, fatigue, palpitations

**Physical Exam**
"cv" waves in JVP, +ve abdominojugular reflux, Kussmaul’s sign, holosystolic murmur at LLSB accentuated by inspiration, left parasternal lift

**Investigations**
ECG: RAE, RVH, AFib
CXR: RAE, RV enlargement
Echo: diagnostic

**Treatment**
Preload reduction (diuretics)
Surgery if: only if other surgery required (e.g. mitral valve replacement)

**Surgical Options**
Annuloplasty (i.e. repair, rarely replacement)

### Mitral Valve Prolapse (MVP)

**Etiology**
Myxomatous degeneration of chordae, thick, bulky leaflets that crowd orifice, associated with Marfan’s syndrome, pectus excavatum, straight back syndrome, other MSK abnormalities; <3% of population

**Pathophysiology**
Mitrail valve displaced into LA during systole; no causal mechanisms found for symptoms

**Symptoms**
Prolonged, stabbing chest pain, dyspnea, anxiety/panic, palpitations, fatigue, presyncope

**Physical Exam**
Auscultation: mid-systolic click (due to billowing of mitral leaflet into LA); tensing of redundant valve tissue); mid to late systolic murmur at apex, accentuated by Valsalva or squat-to-stand maneuvers

**Investigations**
ECG: non-specific ST-T wave changes, paroxysmal SVT, ventricular ectopy
Echo: systolic displacement of thickened mitral valve leaflets into LA

**Treatment**
Asymptomatic: no treatment; reassurance
Symptomatic: β-blockers and avoidance of stimulants (caffeine) for significant palpitations, anticoagulation if AFib

**Surgical Options**
Mitrail valve surgery (repair favoured over replacement) if symptomatic and significant MR
Figure 37. Hemodynamics of aortic stenosis
Stenosis across the aortic valve results in the generation of a significant pressure gradient between the left ventricle and the aorta and a crescendo-decrescendo murmur during systolic contraction. The stenosis decreases the intensity of aortic valve closure hence diminishing S2.

Figure 38. Hemodynamics of aortic regurgitation
Regurgitation across the aortic valve during diastole causes the aortic pressure to rapidly decrease and a decrescendo murmur can be heard at the onset of diastole (after S2 is audible). The presence of regurgitant blood from the aorta increases left-ventricular end-diastolic volume.

Figure 39. Hemodynamics of acute mitral regurgitation
During systolic contraction, blood regurgitates from the left ventricle into the left atrium across the incompetent mitral valve resulting in an audible holosystolic murmur between S1 and S2. The presence of regurgitant blood from the aorta increases left atrial pressures resulting in a tall V-wave (in the JVP).

Figure 40. Hemodynamics of mitral stenosis
First note that the left atrial pressure exceeds the left ventricular pressure during diastole due to mitral stenosis and the consequent generation of a pressure gradient across the left atrium and left ventricle. In diastole the stenotic mitral valve opens which corresponds to the opening snap (OS) and the passage of blood across the mitral stenosis results in an audible decrescendo murmur. Left atrial contraction prior to S1 increases the pressure gradient resulting in accentuation of the murmur before S1 is audible.
Pericardial Disease

Acute Pericarditis

Etiology of Pericarditis/Pericardial Effusion
- idiopathic is most common: presumed to be viral
- infectious
  - viral: Coxsackie virus A, B (most common), echovirus
  - bacterial: *S. pneumoniae*, *S. aureus*
  - TB
  - fungal: histoplasmosis, blastomycosis
- post-MI: acute (direct extension of myocardial inflammation, 1-7 d post-MI), Dressler's syndrome (autoimmune reaction, 2-8 wk post-MI)
- post-cardiac surgery (e.g. CABG), other trauma
- metabolic: uremia (common), hypothyroidism
- neoplasm: Hodgkin's, breast, lung, renal cell carcinoma, melanoma
- collagen vascular disease: SLE, polyarteritis, RA, scleroderma
- vascular: dissecting aneurysm
- other: drugs (e.g. hydralazine), radiation, infiltrative disease (sarcoid)

Signs and Symptoms
- diagnostic triad: chest pain, friction rub, and ECG changes
- pleuritic chest pain: alleviated by sitting up and leaning forward
- pericardial friction rub: may be uni-, bi- or triphasic
- ± fever, malaise

Investigations
- ECG: initially diffuse elevated ST segments ± depressed PR segment, the elevation in the ST segment is concave upwards → 2-5 d later ST isoelectric with T wave flattening and inversion
- CXR: normal heart size, pulmonary infiltrates
- echo: performed to assess for pericardial effusion

Treatment
- treat the underlying disease
- anti-inflammatory agents (high dose NSAIDs/ASA, steroids if severe or recurrent), analgesics

Complications
- recurrent episodes of pericarditis, atrial arrhythmia, pericardial effusion, tamponade, constrictive pericarditis

Pericardial Effusion

Etiology
- transudative (serous)
- CHF, hypoalbuminemia/hypoproteinemia, hypothyroidism
- exudative (serosanguinous or bloody)
  - causes similar to the causes of acute pericarditis
  - may develop acute effusion secondary to hemopericardium (trauma, post-MI myocardial rupture, aortic dissection)
  - physiologic consequences depend on type and volume of effusion, rate of effusion development, and underlying cardiac disease

Signs and Symptoms
- may be asymptomatic or similar to acute pericarditis
- dyspnea, cough
- extra-cardiac (esophageal/recurrent laryngeal nerve/tracheo-bronchial/phrenic nerve irritation)
- JVP increased with dominant “x” descent
- arterial pulse normal to decreased volume, decreased pulse pressure
- auscultation: distant heart sounds ± rub
- Ewart's sign

Investigations
- ECG: low voltage, flat T waves, electrical alternans
- CXR: cardiomegaly, rounded cardiac contour
- echo (procedure of choice): fluid in pericardial sac
- pericardiocentesis: definitive method of determining transudate vs. exudate, identify infectious agents, neoplastic involvement

Treatment
- mild: frequent observation with serial echos, treat underlying cause, anti-inflammatory agents
- severe: treat as in tamponade (see Cardiac Tamponade, C43)
### Cardiac Tamponade

**Etiology**
- major complication of rapidly accumulating pericardial effusion
- cardiac tamponade is a clinical diagnosis
- any cause of pericarditis but especially trauma, malignancy, uremia, proximal aortic dissection with rupture

**Pathophysiology**
- high intra-pericardial pressure → decreased venous return → decreased diastolic ventricular filling → decreased CO → hypotension and venous congestion

**Signs and Symptoms**
- tachypnea, dyspnea, shock, muffled heart sounds
- pulsus paradoxus (inspiratory fall in systolic BP >10 mmHg during quiet breathing)
- JVP “x” descent only, blunted “y” descent
- hepatic congestion/peripheral edema

**Investigations**
- ECG: electrical alternans (pathognomonic variation in R wave amplitude), low voltage
- echo: pericardial effusion, compression of cardiac chambers (RA and RV) in diastole
- cardiac catheterization

**Treatment**
- pericardiocentesis – echo-guided
- pericardiectomy
- avoid diuretics and vasodilators (these decrease venous return to already under-filled RV → decrease LV preload → decrease CO)
- IV fluid may increase CO
- treat underlying cause

### Constrictive Pericarditis

**Etiology**
- chronic pericarditis resulting in fibrosed, thickened, adherent, and/or calcified pericardium
- any cause of acute pericarditis may result in chronic pericarditis
- major causes are idiopathic, post-infectious (viral, TB), radiation, post-cardiac surgery, uremia, MI, collagen vascular disease

**Signs and Symptoms**
- dyspnea, fatigue, palpitations
- abdominal pain
- may mimic CHF (especially right-sided HF)
  - ascites, hepatosplenomegaly, edema
- increased JVP, Kussmaul’s sign (paradoxical increase in JVP with inspiration), Friedreich’s sign (prominent “y” descent)
- BP usually normal (and usually no pulsus paradoxus)
- precordial examination: ± pericardial knock (early diastolic sound)
- see Table 15 for differentiation from cardiac tamponade

**Investigations**
- ECG: non-specific – low voltage, flat T wave, ± AFib
- CXR: pericardial calcification, effusions
- echo/CT/MRI: pericardial thickening
- cardiac catheterization: equalization of end-diastolic chamber pressures (diagnostic)

**Treatment**
- medical: diuretics, salt restriction
- surgical: pericardiectomy (only if refractory to medical therapy)
- prognosis best with idiopathic or infectious cause and worst in post-radiation. Death may result from heart failure

VASCULAR DISEASE

Peripheral Arterial Disease

Peripheral Vascular Anatomy

- see Figure 41

Acute Arterial Occlusion/Insufficiency

Definition

- acute occlusion/rupture of a peripheral artery
- urgent management required: treat within 6 h or irreversible ischemia and myonecrosis may result
- tends to be lower extremity > upper extremity; femoropopliteal > aortoiliac

Etiology and Risk Factors

Table 16. Clinical Categories of Acute Limb Ischemia

</tbody>
</table>

Hypercoagulable States

- congenital
  - group I (reduced anticoagulants): anti-thrombin, protein C, protein S
  - group II: factor V leiden, prothrombin, factor VIII, hyper-homocysteinemia
- acquired: immobility, cancer, pregnancy/OCP, anti-phospholipid antibody syndrome, inflammatory disorders (e.g. IBD), myeloproliferative disorders (e.g. ET), nephrotic syndrome (acquired deficit in protein C and S), disseminated intravascular coagulation (DIC), heparin-induced thrombocytopenia with thrombosis (HITT)
  - for presentation of embolus vs. thrombus see Table 17

Investigations

- history and physical exam: depending on degree of ischemia may have to forego investigations and go straight to OR
- ABI: extension of physical exam, easily performed at bedside
- ECG, troponin: rule out recent MI or arrhythmia
- CBC: rule out leukocytosis, thrombocytosis or recent drop in platelets in patients receiving heparin
- PT/INR: patient anticoagulated/sub-therapeutic INR
- echo: identify wall motion abnormalities, intracardiac thrombus, valvular disease, aortic dissection (type A)
- CT angiogram: underlying athelosclerosis, aneurysm, aortic dissection
- conventional catheter based angiography: can be obtained in OR, prelude to thrombolytics

Treatment

- immediate heparinization with 5000 IU bolus and continuous infusion to maintain PTT >60 s
- if absent power and sensation: emergent revascularization
- if present power and sensation: work-up (including angiogram)
- definitive treatment
  - embolus: embolectomy
  - thrombus: thrombectomy ± bypass graft ± endovascular therapy
  - irreversible ischemia: primary amputation
- identify and treat underlying cause
- continue heparin post-op, start warfarin post-op day 1 x 3 mo depending on underlying etiology

Figure 41. Peripheral vascular anatomy

Hypercoagulable State

Congenital
- Group I (reduced anticoagulants)
  - Antithrombin
  - Protein C
  - Protein S
- Group II (increased coagulants)

### Complications
- compartment syndrome with prolonged ischemia; requires fasciotomy
- renal failure and multi-organ failure due to toxic metabolites from ischemic muscle

### Prognosis
- 12-15% mortality rate
- 5-40% morbidity rate (amputation)

## Chronic Arterial Occlusion/Insufficiency

### Etiology
- predominantly due to atherosclerosis; primarily lower extremities

### Risk Factors
- major: smoking, DM
- minor: HTN, hyperlipidemia, family history, obesity, sedentary lifestyle

### Clinical Features
- claudication
  1. pain with exertion: usually in calves or any exercising muscle group
  2. relieved by short rest: 2 to 5 min, and no postural changes necessary
  3. reproducible: same distance to elicit pain, same location of pain, same amount of rest to relieve pain
- critical limb ischemia
  1. includes rest pain, night pain, tissue loss (ulceration or gangrene)
  2. ankle pressure <40 mmHg, toe pressure <30 mmHg, ABI <0.40
- pulses may be absent at some locations, bruits may be present
- signs of poor perfusion: hair loss, hypertrophic nails, atrophic muscle, skin ulcerations and infections, slow capillary refill, prolonged pallor with elevation and rubor on dependency, venous troughing (collapse of superficial veins of foot)
- other manifestations of atherosclerosis: CVD, CAD, impotence, splanchnic ischemia

### Investigations
- non-invasive
  - routine bloodwork, fasting metabolic profile
  - ABI: take highest brachial and highest ankle [dorsalis pedis (DP) or posterior tibial (PT)] pressures for each side generally
    - ABI <0.90 abnormal, rest pain appears at <0.3 (see Table 18)
  - CTA and MRA: excellent for large arteries (aorta, iliac, femoral, popliteal), may have difficulty with tibial arteries (especially in the presence of disease). Both require IV injection of nephrotoxic contrast (iodinated contrast for CT, gadolinium for MR)
- invasive
  - arteriography: superior resolution to CTA/MRA, better for tibial arteries, can be done intraoperatively

</tbody>
</table>

### Symptoms of Acute Limb Ischemia
- 6 Ps – all may not be present
  - Pain: absent in 20% of cases
  - Pallor: within a few hours becomes mottled cyanosis
  - Paraesthesia: light touch lost first then sensory modalities
  - Paralysis/Power loss: most important, heralds impending gangrene
  - Petechiae/Poikilothermia (cold)
  - Pulselessness: not reliable

### Differential of Claudication

#### Vascular
- Atherosclerotic disease
- Vasculitis (e.g. Buerger’s disease, Takayasu’s arteritis)
- Diabetic neuropathy
- Venous disease (e.g. DVT, varicose veins)
- Popliteal entrapment syndrome (e.g. Baker’s cyst, tumour)

#### Neurologic
- Neuropathic disease (e.g. spinal stenosis)
- Reflex sympathetic dystrophy

#### MSK
- Osteoarthritis
- Rheumatoid arthritis/connective tissue disease
- Remote trauma
Treatment (see Figure 42)

- conservative
  - risk factor modification (smoking cessation, treatment of HTN, hyperlipidemia, DM)
  - exercise program: improves collateral circulation, oxygen extraction at the muscle level
  - foot care (especially in DM): keep wounds clean/dry, avoid trauma and pressure on wounds
- pharmacotherapy
  - antiplatelet agents (ECASA, clopidogrel or more rarely ticlopidine)
  - cilostazol (cAMP-phosphodiesterase inhibitor with antiplatelet and vasodilatory effects) – improves walking distance for some patients with claudication (not available in Canada)
- surgical/endovascular
  - indications: severe lifestyle impairment, vocational impairment, critical ischemia
  - surgical options:
    - endovascular (stenting/angioplasty) (see Medical Imaging, MI28)
    - endarterectomy: removal of plaque and repair with patch (usually distal aorta or common/profunda femoral)
    - bypass graft sites: aortofemoral, axillofemoral, femoropopliteal, distal arterial (see Figure 42)
      - graft choices: vein graft (reversed or in situ), synthetic – polytetrafluoroethylene graft (e.g. Gore-Tex® or Dacron®)
    - chemical sympathectomy: sympathetic plexus destroyed with EtOH injection into nerve plexus, may stimulate vasodilation (rarely effective)
    - amputation: if not suitable for revascularization, persistent serious infections/gangrene

Prognosis

- claudication: conservative therapy: 60-80% improve, 20-30% stay the same, 5-10% deteriorate, 5% will require intervention within 5 yr, <4% will require amputation
- for patients with critical ischemia (rest pain, night pain, ulceration or gangrene): high risk of limb loss

Figure 42. Treatment options for critical limb ischemia

(A) Algorithm for the treatment of critical limb ischemia
(B) Surgical treatment options for the treatment of aortoiliac disease

Hypertension

- see Family Medicine, FM37

Pulmonary Hypertension

- see Respirology, R16
Aortic Disease

Aortic Anatomy

- see Figure 43

Aortic Dissection

Definition
- tear in aortic intima allowing blood to dissect into the media; acute <2 wk (initial mortality 1% per hour for type A dissections), chronic >2 wk (mortality levels up to 75-80%)

Etiology
- most common: HTN → degenerative/cystic changes → damage to aortic media
- other: connective tissue disease (e.g. Marfan’s, Ehlers-Danlos), cystic medial necrosis, atherosclerosis, congenital conditions (e.g. coarctation of aorta, bicuspid aortic valves, patent ductus arteriosus), infection (e.g. syphilis), trauma, arteritis (e.g. Takayasu’s)

Epidemiology
- incidence of 5.2 in 1,000,000
- male:female = 3:2:1
- small increased incidence in African-Canadians (related to higher incidence of HTN)
- lowest incidence in Asians
- peak incidence 50-65 yr old; 20-40 yr old with connective tissue diseases

Clinical Features
- sudden onset tearing chest pain that radiates to back with:
  - HTN (75-85% of patients)
  - asymmetric BPs and pulses between arms (>30 mmHg difference indicates poor prognosis)
  - ischemic syndromes due to occlusion of aortic branches: coronary (MI), carotids (ischemic stroke, Horner's syndrome), splanchic (mesenteric ischemia), renal (AKI), peripheral (ischemic leg), intercostal vessels (spinal cord ischemia)
  - “unseating” of aortic valve cusps (new diastolic murmur in 20-30%)
  - rupture into pleura (dyspnea, hemothorax) or peritoneum (hypotension, shock) or pericardium (cardiac tamponade)
  - syncope

Investigations
- CXR
  - pleural cap (pleural effusion in lung apices)
  - widened mediastinum
  - left pleural effusion with extravasation of blood
- TEE: can visualize aortic valve and thoracic aorta but not abdominal aorta
- ECG: LVH ± ischemic changes, pericarditis, heart block
- CT (gold standard), aortography, MRA: 100% sensitive and specific
- bloodwork: lactate (r/o ischemic gut), amylase (r/o pancreatitis), troponin (r/o MI)

Treatment
- pharmacologic
  - β-blocker to lower BP and decrease cardiac contractility
  - use nondihydropyridine calcium channel blocker if there is a clear contraindication to β-blockers
  - target sBP of 110 mmHg and HR of less than 60 bpm
  - ACEI and/or other vasodilators if insufficient BP or HR control
- surgical
  - urgent surgical consult if thoracic aortic dissection diagnosed or highly suspected
  - resection of segment with intimal tear
  - reconstitution of flow through true lumen
  - replacement of the affected aorta with prosthetic graft
  - correction of any predisposing factors
Post-operative complications: renal failure, intestinal ischemia, stroke, paraplegia, persistent leg ischemia, death
2/3 of patients die of operative or post-operative complications
Type A: requires emergent surgery with cardiopulmonary bypass;
  - hypothermic circulation for transverse arch dissections
  - resuspension of aortic valve
  - aortic valve replacement
  - coronary re-implantation for aortic root involvement
  - initial mortality rate without surgery is 3% per h for first 24 h, 30% 1 wk, 80% 2 wk
Type B: managed medically in absence of malperfusion syndrome
  - <10-20% require urgent operation for complications
  - treatment can be surgical or endovascular
  - with treatment, 60% 5 yr survival, 40% 10 yr survival

Aortic Aneurysm

Definition of Aneurysm
- localized dilatation of an artery having a diameter at least 1.5 times that of the expected normal diameter
  - true aneurysm: involving all vessel wall layers (intima, media, adventitia)
  - false aneurysm (also known as pseudo-aneurysm): disruption of the aortic wall or the anastomotic site between vessel and graft with containment of blood by a fibrous capsule made of surrounding tissue
- aneurysms can rupture, thrombose, embolize, erode, and fistulize

Classification
- thoracic aortic aneurysm (TAA): ascending, transverse arch, descending
- thoracoabdominal
- abdominal aortic aneurysm (AAA): 90-98% are infrarenal

Etiology
- degenerative (atherosclerotic)
- traumatic
- mycotic (Salmonella, Staphylococcus, usually suprarenal aneurysms)
- connective tissue disorder (Marfan syndrome, Ehlers-Danlos syndrome)
- vasculitis
- infectious (syphilis, fungal)
- ascending thoracic aneurysms are associated with bicuspid aortic valve
- risk factors: smoking, HTN, age >70, family history

Epidemiology
- incidence 4.7 to 31.9 per 100 000 for AAA and 5.9 per 100 000 for TAA
- high risk groups
  - 65 yr and older
  - male:female = 3.8:1
  - PVD, CAD, CVD
  - family history of AAA

ACC/AHA 2005 Guidelines define an AAA when the minimum AP diameter of abdominal aorta ≥3.0 cm.
Clinical Features
- common presentation: due to acute expansion or disruption of wall
  - syncope
  - pain (chest, abdominal, flank, back)
  - hypotension
  - palpable pulsatile mass above the umbilicus, pulsatile abdominal mass in two directions (expansible)
  - airway or esophageal obstruction, hoarseness (left recurrent laryngeal nerve paralysis), hemoptysis, or hematemesis (indicates thoracic or thoracoabdominal aortic aneurysm)
  - distal pulses may be intact
- 75% asymptomatic (discovered incidentally)
- uncommon presentation
- ureretic obstruction and hydronephrosis (often with inflammatory aortic aneurysm)
- GI bleed (duodenal mucosal hemorrhage, aortoduodenal fistula)
- aortocaval fistula
- distal embolization (blue toe syndrome)
- associated diseases
  - HTN, PVD, CAD, COPD, renal insufficiency
  - most commonly in the abdominal aorta (50% abdominal aorta, 40% thoracic aorta, 10% ascending aorta)

Investigations
- bloodwork: CBC, electrolytes, urea, creatinine, PTT, INR, type and cross
- abdominal U/S (100% sensitive, up to ± 0.6 cm accuracy in size determination)
- CT (accurate visualization, size determination)
- aortogram (only for EVAR)
- Doppler/duplex (r/o vascular tree aneurysms elsewhere, e.g. popliteal)

Treatment
- conservative
  - cardiovascular risk factor reduction: smoking cessation; control of HTN, DM, and hyperlipidemia
  - regular exercise
  - watchful waiting, U/S every 6 mo to 3 yr depending on size and location
- surgical
  - when risk of rupture greater than or equal to risk of surgery (>5.5 cm)
  - risk of rupture depends on
    - size
    - rate of enlargement (if >0.4 cm/yr)
    - symptoms, comorbidities (HTN, COPD, dissection), smoking
  - elective AAA repair mortality 2-5%; elective TAA repair mortality <10% (highest with proximal aortic and thoracoabdominal repairs)
  - consider revascularization for patients with CAD before elective repair of aneurysm
  - indications
    - general: ruptured, symptomatic, mycotic, associated with acute Type A dissection or complicated Type B dissection or when risk of rupture is greater than risk of surgery (size >5.5 cm or >2x normal lumen size)
    - ascending thoracic aortic aneurysms
      - symptomatic, enlarging, diameter >5.5 cm or >2x normal lumen size; >4.5 cm and aortic regurgitation (annuloaortic ectasia); ≥4.5-5.5 cm in Marfan syndrome
    - contraindications: life expectancy <1 yr, terminal disease (e.g. cancer), significant comorbidities (e.g. recent MI, unstable angina), decreased mental acuity, advanced age
  - surgical options
    - open surgery (laparotomy or retroperitoneal) with graft replacement
      - possible complications
        - early: renal failure, spinal cord injury (paraparesis or paraplegia), impotence, arterial thrombosis, anastomotic rupture or bleeding, peripheral emboli
        - late: graft infection/thrombosis, aortoenteric fistula, anastomotic (pseudo) aneurysm
    - endovascular aneurysm repair (EVAR)
      - newer procedure; high success rates in patients with suitable anatomy and experienced centres
      - advantages: decreased morbidity and mortality, procedure time, need for transfusion, ICU admissions, length of hospitalization, and recovery time
      - disadvantages: endoleak rates as high as 20-30%, device failure increasing as longer follow-up periods are achieved, re-intervention rates 10-30%, cost-effectiveness is an issue (devices are very expensive), radiation exposure
      - complications
        - early: immediate conversion to open repair, groin hematoma, arterial thrombosis, iliac artery rupture, and thromboemboli
        - late: endoleak (see sidebar), severe graft kinking, migration, thrombosis, rupture of aneurysm
Peripheral Venous Disease

Deep Venous Thromboembolism

• see Hematology, H31

Superficial Venous Thrombosis (SVT)

Definition
• erythema, induration, and tenderness along the superficial vein; usually spontaneous but can follow venous cannulation

Etiology
• infectious: suppurative phlebitis (complication of IV cannulation; associated with fever/chills)
• trauma
• inflammatory: varicose veins, migratory superficial thrombophlebitis, Buerger’s disease, SLE
• hematologic: polycythemia, thrombocytosis
• neoplastic: occult malignancy (especially pancreatic)
• idiopathic

Clinical Features
• most common in greater saphenous vein and its tributaries
• pain and cord-like swelling along course of involved vein
• areas of induration, erythema, and tenderness correspond to dilated and often thrombosed superficial veins
• complications
  ▪ simultaneous DVT (up to 20% of cases), PE (rare unless DVT)
  ▪ recurrent superficial thrombophlebitis

Investigations
• non-invasive tests (e.g. Doppler) to exclude associated DVT

Treatment
• conservative
  ▪ moist heat, compression bandages, mild analgesic, anti-inflammatory and anti-platelet (e.g. ASA), LMWH, ambulation
• surgical excision of involved vein
  ▪ indication: failure of conservative measures (symptoms that persist over 2 wk)
  ▪ suppurative thrombophlebitis: broad-spectrum IV antibiotics and excision

Varicose Veins

Definition
• distention of tortuous superficial veins resulting from incompetent valves in the deep, superficial, or perforator systems
• distribution: greater saphenous vein and tributaries (most common), esophagus, anorectum, scrotum

Etiology
• primary
  ▪ main factor: inherited structural weakness of valves
  ▪ contributing factors: increasing age, female gender, OCP use, occupations requiring long hours of standing, pregnancy, obesity
• secondary
  ▪ malignant pelvic tumours with venous compression
  ▪ congenital anomalies, arteriovenous fistulae

Epidemiology
• primary varicose veins are the most common form of venous disorder of lower extremity
• 10-20% of population
Clinical Features
- diffuse aching, fullness/tightness, nocturnal cramping
- aggravated by prolonged standing (end of day), premenstrual
- visible long, dilated and tortuous superficial veins along thigh and leg
- ulceration, hyperpigmentation, and induration (secondary varicosities)
- Brodie-Trendelenberg test (valvular competence test)
- with patient supine, raise leg and compress saphenous vein at thigh, have patient stand – if veins fill quickly from top down then incompetent valves; use multiple tourniquets to localize incompetent veins

Complications
- recurrent superficial thrombophlebitis
- hemorrhage: external or subcutaneous
- ulceration, eczema, lipodermatosclerosis, and hyperpigmentation

Treatment
- largely a cosmetic problem
- conservative: elevation of leg and/or elastic compression stockings
- surgical: high ligation and stripping of the long saphenous vein and its tributaries, ultrasound-guided foam sclerotherapy, endovenous laser therapy (EVLT)
- indications for surgery: symptomatic varix (pain, bleeding, recurrent thrombophlebitis), tissue changes (hyperpigmentation, ulceration), failure of conservative treatment, cosmetics

Prognosis
- benign course with predictable complications
- almost 100% symptomatic relief with treatment if varicosities are primary
- good cosmetic results with treatment
- significant post-operative recurrence, especially with sclerosing agent injection

Chronic Venous Insufficiency (CVI)

Definition
- venous insufficiency and skin damage

Etiology
- calf muscle pump dysfunction and valvular incompetence (valvular reflux) due to phlebitis, varicosities, or DVT
- venous obstruction
- AV fistulas, venous malformations

Clinical Features
- pain (most common), ankle and calf edema – relieved by foot elevation
- pruritus, brownish hyperpigmentation (hemosiderin deposits)
- stasis dermatitis, subcutaneous fibrosis if chronic (lipodermatosclerosis)
- ulceration: shallow, above medial malleolus, weeping (wet), painless, irregular outline
- signs of DVT/varicose veins/thrombophlebitis

Investigations
- ambulatory venous pressure measurement (gold standard)
- Doppler U/S (most commonly used)
- photoplethysmography

Treatment
- conservative
  - elastic compression stockings, leg elevation, avoid prolonged sitting/standing
  - ulcers: zinc-oxide wraps, split-thickness skin grafts, antibiotics, debridement
- surgical
  - if conservative measures fail, if recurrent/large ulcers
  - surgical ligation of perforators in region of ulcer, (GSV/LSV ligation and stripping)
**Lymphedema**

**Definition**
- obstruction of lymphatic drainage resulting in edema with high protein content

**Etiology**
- primary: Milroy’s syndrome (congenital hereditary lymphedema)
- secondary:
  - infection: filariasis (#1 cause worldwide), post-operative
  - malignant infiltration: axillary, groin or intrapelvic
  - radiation/surgery (axillary, groin lymph node removal): #1 cause in North America

**Clinical Features**
- classically non-pitting edema
- impaired limb mobility, discomfort/pain, psychological distress

**Treatment**
- avoid limb injury (can precipitate or worsen lymphedema)
- skin hygiene
  - daily skin care with moisturizers
  - topical treatment of fungal infection; systemic treatment of bacterial infection
- external support
  - intensive: compression bandages
  - maintenance: lymphedema sleeve
- exercise
  - gentle daily exercise of affected limb, gradually increasing ROM
  - must wear a compression sleeve/bandages when doing exercises
- massage and manual lymph drainage therapy

**Prognosis**
- if left untreated becomes resistant to treatment due to subcutaneous fibrosis
- cellulitis causes rapid increase in swelling: can lead to sepsis and death
**Common Medications**

</thead>
<tbody>
<tr>
<td><strong>ANGIOTENSIN CONVERTING ENZYME INHIBITORS (ACEI)</strong></td>
<td>enalapril (Vasotec®), perindopril (Coversyl®), ramipril (Altace®), lisinopril (Zestril®)</td>
<td>Inhibit ACE-mediated conversion of angiotensin I to angiotensin II (AT II), causing peripheral vasodilation and decreased aldosterone synthesis</td>
<td>HTN, CAD, CHF, post-MI, DM</td>
<td>Dry cough, 10% hypotension, fatigue, hyperkalemia, renal insufficiency, angioedema</td>
<td>Bilateral renal artery stenosis, pregnancy, caution in decreased GFR</td>
</tr>
<tr>
<td><strong>ANGIOTENSIN II RECEPTOR BLOCKERS (ARBs)</strong></td>
<td>candesartan, irbesartan, valsartan</td>
<td>Block AT II receptors, causing similar effects to ACEI</td>
<td>Same as ACEI, although evidence is generally less for ARBs. Often used when ACEI are not tolerated</td>
<td>Similar to ACEI, but do not cause dry cough</td>
<td>Same as ACEI</td>
</tr>
<tr>
<td><strong>DIRECT RENIN INHIBITORS (DRIs)</strong></td>
<td>aliskiren</td>
<td>Directly blocks renin thus inhibiting the conversion of angiotensinogen to angiotensin I. This also causes a decrease in AT II</td>
<td>HTN (exact role of this drug remains unclear)</td>
<td>Diarrhea, hyperkalemia (higher risk if used with an ACEI), rash, cough, angioedema, reflux, hypotension, rhabdomyolysis, seizure</td>
<td>Pregnancy, severe renal impairment</td>
</tr>
<tr>
<td><strong>β-BLOCKERS</strong></td>
<td>atenolol, metoprolol, bisoprolol</td>
<td>Block β1-adrenergic receptors, decreasing HR, BP, contractility, and myocardial oxygen demand, slow conduction through the AV node</td>
<td>HTN, CAD, acute MI, post-MI, CHF (start low and go slow), AFib, SVT</td>
<td>Hypotension, fatigue, light-headedness, depression, bradycardia, hyperkalemia, bronchospasm, impotence, depression of counterregulatory response to hypoglycemia, exacerbation of Raynaud’s phenomenon and claudication</td>
<td>Sinus bradycardia, 2nd or 3rd degree heart block, hypotension, WPW. Caution in asthma, claudication, Raynaud’s phenomenon, and decompensated CHF</td>
</tr>
<tr>
<td><strong>CALCIUM CHANNEL BLOCKERS (CCBs)</strong></td>
<td>diltiazem, verapamil</td>
<td>Block smooth muscle and myocardial calcium channels causing effects similar to β-blockers Also vasodilate</td>
<td>HTN, CAD, SVT, diastolic dysfunction</td>
<td>Hypotension, bradycardia, edema Negative inotrope</td>
<td>Sinus bradycardia, 2nd or 3rd degree heart block, hypotension, WPW, CHF</td>
</tr>
<tr>
<td><strong>DIURETICS</strong></td>
<td>hydrochlorothiazide, chlorothalidone, metolazone</td>
<td>Reduce Na⁺ reabsorption in the distal convoluted tubule (DCT)</td>
<td>HTN (drugs of choice for uncomplicated HTN)</td>
<td>Hypotension, hypokalemia, polyuria</td>
<td>Sulfur allergy, pregnancy</td>
</tr>
<tr>
<td></td>
<td>furosemide (Lasix®)</td>
<td>Blocks Na⁺/K⁺-ATPase in the loop of Henle</td>
<td>CHF, pulmonary or peripheral edema</td>
<td>Hypovolemia, hypokalemic metabolic alkalosis</td>
<td>Hypovolemia, hypokalemia</td>
</tr>
<tr>
<td></td>
<td>spironolactone, eplerenone</td>
<td>Antagonize aldosterone receptors</td>
<td>HTN, CHF, hypokalemia</td>
<td>Edema, hyperkalemia, gynecomastia</td>
<td>Renal insufficiency, hyperkalemia, pregnancy</td>
</tr>
<tr>
<td><strong>INOTROPES</strong></td>
<td>digoxin (Lanoxin®)</td>
<td>Inhibit Na⁺/K⁺-ATPase, leading to increased intracellular Na⁺ and Ca²⁺ concentration and increased myocardial contractility. Also slows conduction through the AV node</td>
<td>CHF, AFib</td>
<td>AV block, tachyarrhythmias, bradyarrhythmias, blurred or yellow vision (van Gogh syndrome), anorexia, nausea and vomiting</td>
<td>2nd or 3rd degree AV block, hypokalemia, WPW</td>
</tr>
</tbody>

<tr>
<td><strong>ANTICOAGULANTS</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Coumarins</td>
<td>warfarin (Coumadin®)</td>
<td>Antagonizes vitamin K, leading to decreased synthesis of clotting factors II, VII, IX, and X</td>
<td>AFib, LV dysfunction, prosthetic valves</td>
<td>Bleeding (by far the most important side effect), paradoxical thrombosis, skin necrosis</td>
<td>Recent surgery or bleeding, bleeding diathesis, pregnancy</td>
</tr>
<tr>
<td>Heparins</td>
<td>Unfractionated heparin, LMWHs: dalteparin, enoxaparin, tinzaparin</td>
<td>Antithrombin III agonist, leading to decreased clotting factor activity</td>
<td>Acute MI; when immediate anticoagulant effect needed</td>
<td>Bleeding, osteoporosis, heparin-induced thrombocytopenia (less in LMWHs)</td>
<td>Recent surgery or bleeding, bleeding diathesis, thrombocytopenia, renal insufficiency (for LMWHs)</td>
</tr>
<tr>
<td>Direct thrombin inhibitors</td>
<td>dabigatran, melagatran</td>
<td>Competitive, direct thrombin inhibitor; thrombin enables fibrinogen conversion to fibrin during the coagulation cascade, thereby preventing thrombus development</td>
<td>Atrial fibrillation</td>
<td>Bleeding, GI upset</td>
<td>Severe renal impairment, recent surgery, active bleeding</td>
</tr>
<tr>
<td>Direct Factor Xa inhibitors</td>
<td>rivaroxaban</td>
<td>Direct, selective and reversible inhibition of factor Xa in both the intrinsic and extrinsic coagulation pathways</td>
<td>Atrial fibrillation</td>
<td>Bleeding, GI upset, elevated liver enzymes</td>
<td>Hepatic disease, active bleeding, bleeding diathesis, pregnancy, lactation</td>
</tr>
<tr>

<tr>
<td>Salicylates</td>
<td>ASA (Aspirin®)</td>
<td>Irreversibly acetylates platelet COX-1, preventing thromboxane A2-mediated platelet aggregation</td>
<td>CAD, acute MI, post-MI, post-PCI, CABG</td>
<td>Bleeding, GI ulceration, impaired renal perfusion</td>
<td>Active bleeding or peptic ulcer disease (PUD)</td>
</tr>
<tr>
<td>Thienopyridines</td>
<td>clopidogrel (Plavix®), ticlopidine (Ticlid®)</td>
<td>Block platelet ADP receptors</td>
<td>Acute MI, post-MI, post-PCI, CABG</td>
<td>Bleeding, thrombotic thrombocytopenic purpura, neutropenia (ticlopidine)</td>
<td>Active bleeding or PUD</td>
</tr>
<tr>
<td>GPIIb/IIIa inhibitors</td>
<td>eptifibatide, tirofiban, abciximab</td>
<td>Block binding of fibrinogen to Gp IIb/IIIa</td>
<td>Acute MI, particularly if PCI is planned</td>
<td>Bleeding</td>
<td>Recent surgery or bleeding, bleeding diathesis</td>
</tr>
<tr>
<td><strong>THROMBOLYTICS</strong></td>
<td>alteplase, reteplase, tenecteplase, streptokinase</td>
<td>Convert circulating plasminogen to plasmin, which lyses cross-linked fibrin</td>
<td>Acute STEMI</td>
<td>Bleeding</td>
<td>See Table 6, C25</td>
</tr>
<tr>
<td><strong>NITRATES</strong></td>
<td>nitroglycerin</td>
<td>Relax vascular smooth muscle, producing venous and arteriolar dilation</td>
<td>CAD, MI, CHF (isosorbide dinitrate plus hydralazine)</td>
<td>Headache, dizziness, weakness, postural hypotension</td>
<td>Concurrent use of cGMP phosphodiesterase inhibitors, angle closure glaucoma, increased intracranial pressure</td>
</tr>
<tr>
<td><strong>LIPID LOWERING AGENTS</strong></td>
<td></td>

General Principles

Drug Nomenclature

- **chemical name**: describes chemical structure; same in all countries
  - e.g. N-(4-hydroxyphenyl)acetamide is acetaminophen
- **drug identification number (DIN) or national drug code (NDC)**: DIN assigned by Health Canada; NDC assigned by FDA (US)
- **non-proprietary name**: approved name (post-phase III trial), official name (listed in pharmacopoeia), or generic name (off-patent)
  - e.g. acetaminophen
- **proprietary (trade) name**: the brand name or registered trademark
  - e.g. Tylenol®
- **street name**: slang term used for a drug of abuse

Phases of Clinical Testing

- **phase I**: first administration to healthy human volunteers, following animal studies; to determine PK and PD
- **phase II**: first administration to patients, small sample sizes; to determine initial safety and effectiveness, dose range, PK, PD
- **phase III**: large sample sizes, often double-blind RCT; comparative (new drug vs. placebo or standard of care) to establish safety and efficacy
- **phase IV**: post-marketing surveillance, wide distribution; to determine rare adverse reactions, effects of long-term use, ideal dosing, effects in real world practice

Drug Administration

- choice of route of administration depends on
  - drug properties
  - local and systemic effects (limiting action or adverse events)
  - desired onset and/or duration of action
  - patient characteristics

<table>

</tbody>
</table>

At the time of drug launch, only data from phases I-III are available; thus true effectiveness (in contrast to efficacy) and safety may be unknown because real-world patients and usage patterns sometimes differ significantly from those in premarket phases.

Common Latin Abbreviations

- **q**: each, every
- **OD/bid/tid/qid**: once/twice/three/four times a day

### Pharmacokinetics (PK)

- **study of “what the body does to a drug”**
- **definition:** relationship between drug administration, time-course/rate of distribution, concentrational changes in the body compartments, and the drug’s removal from the body

#### Absorption

- **definition:** movement of the drug from the site of administration into plasma

#### Mechanisms of Drug Absorption

- most drugs are absorbed into the systemic circulation via passive diffusion
- other mechanisms: active transport, facilitated diffusion, pinocytosis/phagocytosis

#### Factors Affecting the Rate and Extent of Drug Absorption

- **partition coefficient** of a drug ($P_{ow}$), i.e. its relative solubility in oil (lipid) vs. water
- **local blood flow** at the site of administration (e.g. sublingual vessels facilitate rapid absorption from SL)
- **molecular size** (e.g. small molecular weight drugs absorb faster)
- **pH** and **drug ionization**
  - drugs are usually weak acids (e.g. acetylsalicylic acid) or weak bases (e.g. ketoconazole) and thus have both ionized and non-ionized forms
  - body compartment pH and drug $pK_a$ determine the ratio of ionized:non-ionized ratio (using the Henderson-Hasselbach equation)
  - non-ionized forms cross cell membranes much faster than ionized (charged) forms
- **total surface area for absorption**
  - small intestinal villi (large surface area) is the primary site of absorption for most oral drugs

#### Bioavailability (F)

- **definition:** fraction of dose after administration that reaches systemic circulation in an unchanged state
- affected by: drug absorption, gut metabolism, and hepatic first-pass effect
- IV dose has 100% bioavailability ($F = 1$)
- drugs with a low bioavailability by PO may require a much larger oral dose when compared to the IV dose (e.g. $\beta$-blockers: metoprolol 5 mg IV vs. metoprolol 50 mg PO)

#### First-Pass Effect

- **definition:** drug metabolism by the liver and sometimes the gut before it reaches systemic circulation, resulting in reduced drug bioavailability
- occurs with PO administration of a drug: GI tract (absorption) $\rightarrow$ portal vein to liver (first-pass metabolism) $\rightarrow$ systemic circulation
- occurs to much lesser extent with PR administration because drug absorbed in colon bypasses the portal system: colon (absorption) $\rightarrow$ internal pudendal veins $\rightarrow$ IVC $\rightarrow$ systemic circulation

---

**Partition Coefficient ($P_{ow}$)**

- Ratio of a drug’s solubility in oil/lipid (e.g. cell membrane) as compared to water (e.g. extracellular fluid)
- A large $P_{ow}$ (e.g. anesthetics) means that a drug is highly soluble in lipid and will cross membranes easily

**Drug Ionization Reaction and the Henderson-Hasselbach Equation**

- for a weak acid: $HA \rightarrow A^{-} + H^{+}$; $pK_a = pH + \log [HA/A^{-}]$
- e.g. drug $pK_a = 4.4$ at a gastric pH of 1.4, non-ionized:ionized $= HA:A^{-} = 1:0.001$
- Thus, weak acids are mainly non-ionized and more readily absorbed in stomach.

- for a weak base: $B^{-} + H^{+}$; $pK_b = pH + \log [B^{-}/B]$
- Weak bases more readily absorbed in small intestine (pH ~6.0-9.0)

**Examples of Drugs with High First Pass Effect (Hepatic Extraction)**

- Levodopa
- Morphine
- Propranolol
- Lidocaine
- Organic nitrates

**Examples of Drugs with Low First Pass Effect**

- Diazepam
- Digoxin
- Phenytoin
- Warfarin
**Efflux Pump**
- P-glycoprotein (Pgp) is a protein in the GI tract, renal epithelium, and elsewhere that acts as a multidrug efflux pump involved in the transport of drugs out of cells
- acts to reduce intestinal absorption and enhance renal elimination of certain drugs, e.g. digoxin, dabigatran, etoposide, paclitaxel, tacrolimus, cyclosporine
- some drugs (e.g. macrolide antibiotics) inhibit Pgp function, leading to increased levels of Pgp substrates. Pgp inducers (e.g. St. John’s Wort) do the opposite
- some tumours overexpress Pgp leading to multi-drug resistance to chemotherapy agents

**Distribution**
- definition: movement of drugs between different body compartments and to the site of action
- major body fluid compartments: plasma, interstitial fluid, intracellular fluid, transcellular fluid (e.g. CSF, peritoneal, pleural)
- tissue compartments: fat, brain

**Factors Affecting the Rate and Extent of Drug Distribution**
- physicochemical properties of the drug (e.g. partition coefficient)
- pH of fluid
- plasma protein binding
- binding within compartments (depots, e.g. % body fat)
- cardiac output
- regional blood flow

**Volume of Distribution (Vd)**
- maximum actual \(V_d\) (anatomic fluid volume accessible to drug) = total body water (TBW~40 L for average adult) (see Figure 1)
- \(V_d\): the apparent volume of fluid into which a drug dissolves
  - a calculated value = amount of drug in body + plasma drug concentration
  - a theoretical value that does not correspond to an anatomical space (can exceed TBW)
- the value takes into account drug distribution into tissues and protein binding
- small \(V_d\) corresponds to a drug which concentrates in plasma and/or binds plasma proteins to a high degree
- large \(V_d\) corresponds to a drug which distributes into tissues; most is not in blood (measured) space, and it therefore “appears” to distribute in a large volume
- volume of distribution of plasma-protein bound drugs can be altered by liver and kidney disease
- example: amiodarone distributes into TBW (actual \(V_d = 40 \text{ L}\)), but it also concentrates in fat tissues giving instead an apparent \(V_d\) of 400 L; i.e. to achieve a given plasma concentration of amiodarone, we dose as though the drug distributes into 400 L of body fluid

**Plasma Protein Binding**
- drug molecules in the blood exist in an equilibrium of two forms:
  1. bound to plasma proteins
    - acidic drugs bind to albumin
    - basic drugs bind to α1-acid glycoprotein
  2. free or unbound
    - can leave the circulation to distribute into tissues and exert an effect; subject to metabolism and elimination
- bound fraction is determined by
  - drug concentration, binding affinity, and plasma protein concentration (# of binding sites)
- reduced # of binding sites (e.g. hypoalbuminemia) or saturation of binding sites (e.g. competition/displacement) may result in a an increase in free drug concentration, potentially leading to toxicity (see sidebar). However, more commonly most free drug will be metabolized and toxicity will not be seen

**Depots**
- a body compartment where drug molecules tend to be stored and released slowly over a long period of time
- fat is a depot for very lipid soluble drugs (e.g. diazepam)
- some oil-based medications are injected IM for slow release (e.g. depot medroxyprogesterone acetate q3mo; depot risperidone q2wks)

**Barriers (relative)**
- body structures that limit or prevent diffusion of drug molecules
  - e.g. the placenta or blood brain barrier (BBB – a barrier composed of tight junctions between capillary endothelial cells and astrocytes)

---

**Figure 1. Distribution of total body water (TBW)**

- Intravascular Plasma 4%
- Intracellular Fluid 40-44%
- Extracellular Fluid 16-20%
- Total Body Water 60% of body weight

**Special consideration must be given in dosing patients in hypoalbuminemic states (liver failure or nephrotic syndrome) to prevent drug toxicity.**
**Highly protein-bound drugs (e.g. warfarin, digoxin, diazepam, furosemide, amoxicillin, amitriptyline) will exert a greater effect in these patients than in healthy individuals because of higher levels of free drug.

**Main Factors Governing Penetration of Blood Brain Barrier (BBB)**
- Small molecular size (<500 Daltons)
- High lipid solubility
- Active transport mechanisms (e.g. Pgp multidrug efflux pump)

**Many Drugs Cross BBB:**
- General anesthetics
- Alcohol
- Nicotine
- Caffeine
- L-dopa
- Opioids
- Psychotropic medications
In many of these barriers result, in part, from the activity of multidrug efflux pumps (e.g. Pgp) which serve as a natural defense mechanism against drugs and xenobiotics. need to consider dosing route if drugs are meant to cross these barriers.

### Metabolism (Biotransformation)

- **Definition:** Chemical transformation of a drug in vivo
- **Sites of Biotransformation:** Liver (main), GI tract, lung, plasma, kidney
- **Goal:** To make compounds more hydrophilic to enhance renal elimination
- **As a result of the process of biotransformation:**
  - A pro-drug may be **activated** (e.g. tamoxifen to endoxifen; codeine to morphine)
  - A drug may be **changed** to another active metabolite (e.g. diazepam to oxazepam)
  - A drug may be **changed** to a toxic metabolite (e.g. meperidine to normeperidine)
  - A drug may be **inactivated** (most drugs)

#### Drug Metabolizing Pathways

- **Phase I (P450) reactions**
  - Small molecular changes introduce or unmask polar chemical groups on a parent compound to increase its water solubility (e.g. oxidation-reduction, hydrolysis, hydroxylation); the change in $P_{ow}$ is typically minimal compared to phase II, and often phase I places a polar ‘handle’ on a lipophilic drug to allow for phase II
  - Mediated by cytochrome P450 enzymes found in the endoplasmic reticulum
  - Product of the reaction can be excreted or undergo further phase II reactions
- **Phase II (conjugation) reactions**
  - Conjugation with large polar endogenous substrates (e.g. glucuronidation, glutathione conjugation, sulfation)
  - Dramatically increases water solubility and renal elimination
  - Can occur independently of phase I reactions

#### Factors Affecting Drug Biotransformation

- **Genetic polymorphism** of metabolizing enzymes
  - Individuals may metabolize drugs faster or slower depending on their genotype resulting in poor, intermediate, extensive or ultrarapid metabolizers
  - May lead to toxicity or ineffectiveness of a drug at a normal dose, e.g. tamoxifen and codeine are prodrugs activated by CYP2D6 (nonfunctional alleles reduce effectiveness, whereas overactive/duplicated alleles impart “ultrarapid metabolizer” phenotype), while warfarin is metabolized by CYP2C9 (nonfunctional alleles lead to lower dose requirements)
- **Enzyme inhibition** may sometimes be due to other drugs
  - P450 enzyme inhibition leads to an increased concentration and bioavailability of the substrate drug
  - E.g. erythromycin, ketoconazole, indinavir and grapefruit juice (CYP3A4 inhibitors) can predispose a patient to drug toxicity from other drugs also metabolized by CYP3A4 (e.g. simvastatin)
- **Enzyme induction**
  - Certain medications enhance gene transcription leading to an increase in the activity of a metabolizing enzyme
  - A drug may induce its own metabolism (e.g. carbamazepine) or that of other drugs (e.g. phenobarbital can induce the metabolism of OCP and bilirubin) by inducing the P450 enzyme system
- **Liver dysfunction** (e.g. hepatitis, alcoholic liver, biliary cirrhosis, or hepatocellular carcinoma) may decrease drug metabolism but this may not be clinically significant due to the liver’s reserve capacity
- **Renal disease** often results in decreased drug clearance if it is renally cleared
- **Extravasation of age** (neonates or elderly) have reduced biotransformation capacity, and doses should be adjusted accordingly
- **Nutrition**
  - Insufficient protein and fatty acid intake decrease P450 biotransformation
  - Vitamin and mineral deficiencies may also impact metabolizing enzymes
- **Alcohol:** While acute alcohol ingestion inhibits CYP2E1, chronic consumption can induce CYP2E1 and increase the risk of hepatocellular damage from acetaminophen by increasing the generation of acetaminophen’s toxic metabolite
- **Smoking** can induce CYP1A2, thus increasing the metabolism of some drugs (e.g. smokers may require higher doses of theophylline, which is metabolized by CYP1A2)

### Notes

- The very young and the very old are very sensitive to the actions of drugs.

### Common Examples of P450 Inhibitors and Inducers

Note: The above list is not exhaustive.
Elimination

- definition: removal of drug from the body

Routes of Drug Elimination

- kidney (main organ of elimination)
  - two mechanisms for renal elimination
    1. glomerular filtration
       - a passive process, so that only the free drug fraction can be filtered
       - drug filtration rate depends on GFR, degree of protein binding of drug, and size of drug
    2. tubular secretion
       - an active process that is saturable, allowing both protein-bound and free drug fractions to be excreted
       - distinct transport mechanisms for weak acids (e.g. penicillin, salicylic acid, probenecid, chlorothiazide) and weak bases (e.g. quinine, quaternary ammonium compounds such as choline)
       - drugs may competitively block mutual secretion if both use the same secretion system
       - tubular reabsorption: drugs can be passively reabsorbed back to the systemic circulation, countering elimination mechanisms
    - renal function (decreases with age and is affected by many disease states) is assessed clinically by using serum creatinine (Cr) levels
    - stool
      - some drugs and metabolites are actively excreted in the bile (e.g. corticosteroids) or directly into the intestinal tract from systemic circulation
      - enterohepatic reabsorption counteracts stool elimination, and thus can substantially prolong the drug's duration in the body
      - some glucuronic acid conjugates that are excreted in the bile will be hydrolyzed in the intestines by bacteria back to its original form that can be systemically reabsorbed
    - lungs
      - elimination of anesthetic gases and vapours by exhalation
    - saliva
      - saliva concentrations of some drugs parallel their plasma levels (e.g. rifampin)

Pharmacokinetic Calculation

- definition: the quantitative description of the rates of the various steps of drug disposition (i.e. how drugs move through the body)
- the pharmacokinetic principles of ADME (absorption, distribution, metabolism, and elimination) can be graphically represented on the concentration vs. time graph (see Figure 2)

Time-Course of Drug Action

- many kinetic parameters are measured using IV dosing, such that absorption is immediate and distribution for most drugs is rapid; thus elimination is the main process being measured
- the concentration axis is converted to a log<sub>10</sub> concentration to allow for easier mathematical calculations (see Figure 3)

Half-Life (t<sub>1/2</sub>)

- definition: time taken for the serum drug level to fall 50% during elimination
- for drugs with first order kinetics: takes five half-lives to reach steady state with repeated dosing or for drug elimination once dosing is stopped
- see sidebar for calculation

<td>93.8%</td>
<td>96.9%</td>
</tr>
</tbody>
</table>

Steady State

- drug concentration stays constant when the same amount of drug entering the system is eliminated from the system
- appropriate timing is important for therapeutic monitoring since drug levels are reliable only when the drug has reached steady state (see Figure 4)
• special situations
  ▪ use a loading dose for drugs with a long half-life and when there is clinical need to rapidly achieve therapeutic levels (e.g. amiodarone, digoxin, phenytoin)
  ▪ use continuous infusion for drugs with a very short half-life and when there is need for a long-term effect and multiple or frequently repeated doses are too inconvenient (e.g. nitroprusside, insulin, unfractionated heparin)

Clearance (Cl)
• a quantitative measurement of the body fluid volume from which a substance is removed per unit time
• Cl = rate of elimination of drug ÷ plasma drug concentration
• must consider clearance from a specific part of the body and total body clearance

Elimination Kinetics (see Figure 5)
• first-order kinetics (most common type)
  ▪ constant fraction of drug eliminated per unit time
  ▪ some drugs can follow first-order kinetics until elimination is saturated (usually at large doses) at which point the clearance decreases
  ▪ becomes linear relationship when plotted on a log(concentration) vs. time graph (see Figure 3)
• zero-order kinetics (less common, associated with toxicities, e.g. alcohol)
  ▪ a constant rate of drug eliminated regardless of concentration; concept of half-life does not apply

Table 2. Loading vs. Maintenance Dosing

<table>
<thead>
<tr>
<th>Loading Dose</th>
<th>Maintenance Dose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use when you need an IMMEDIATE effect</td>
<td>After a loading dose OR beginning with maintenance doses</td>
</tr>
<tr>
<td>Often parenteral medication</td>
<td>Steady-state levels achieved after ~5 half lives</td>
</tr>
<tr>
<td>Rationale: give large dose of medication to &quot;fill up&quot; the volume of distribution</td>
<td>Can be given as either a continuous infusion (relatively rare, short half-life drug) OR much more commonly as intermittent doses</td>
</tr>
</tbody>
</table>

Pharmacodynamics (PD)
• study of “what a drug does to the body”

Dose-Response Relationship
• graded dose-response relationships: the response of the drug reflects the number of receptors that are effectively occupied

Efficacy
• measured as $E_{\text{max}}$ = the maximal response that a drug can elicit in an RCT or under optimal circumstances (see Figure 6)

Potency
• measured as $E_{50}$ = the effective concentration of a drug needed to produce 50% of $E_{\text{max}}$ (see Figure 6)
• the drug that reaches its $E_{50}$ at the lower dose is the more potent
• overcome low potency by increasing the dose of the drug (e.g. 30 mg vs. 15 mg) to achieve desired response, provided that the higher dose not cause adverse effects
**Effects of Drugs on Receptors**

**Agonists**
- drugs that mimic endogenous ligands and exert an effect
- have two main properties
  - **affinity**: the ability of the agonist to bind to the receptor (e.g., the β2-agonist salbutamol has greater affinity for β2-receptors than β1-receptors)
  - **efficacy**: the ability to recapitulate endogenous response via the receptor interaction (e.g., binding of salbutamol to β2-receptors results in smooth muscle relaxation)
- **full agonists**: can elicit a maximal effect at a receptor
- **partial agonists**: can only elicit a partial effect, no matter how high the concentration
  - e.g., reduced efficacy compared to full agonists

**Antagonists**
- drugs that have affinity (can bind to a receptor) but exert no effect
- these are drugs that block the action of an agonist or of an endogenous ligand
- **chemical antagonism**: direct chemical interaction between agonist and antagonist that prevents agonist binding to receptor
  - e.g., chelating agents for removal of heavy metals
- **functional antagonism**: two agonists that act independently at different receptors but have opposite physiological effects
  - e.g., acetylcholine at the muscarinic receptor decreases HR, constricts pupils, and stimulates intestinal motility; whereas epinephrine at the adrenergic receptor increases HR, dilates pupils, and decreases intestinal motility
- **reversible competitive antagonism** (most common in clinical practice, see Figure 8)
  - antagonist reversibly binds to the same receptor as the agonist, thus displacing it (e.g., naloxone is an antagonist to morphine or heroin)
- **irreversible antagonism** (see Figure 9)
  - antagonist irreversibly binds to the same receptor as the agonist, blocking it from binding (e.g., Phenoxybenzamine forms a permanent covalent bond with adrenergic receptors preventing adrenaline and noradrenaline from binding)
- **non-competitive antagonism** (see Figure 7)
  - antagonist binds to an alternate site separate but near the agonist site, producing allosteric effects that change the ability of the agonist to bind (e.g., organophosphates irreversibly bind acetylcholinesterase)

![Figure 7. Mechanism of agonists and antagonists](image)

**Figure 8. The log(dose)-response curve for competitive reversible antagonism**

A → C increasing dose of competitive antagonist
At each dose of antagonist, increasing the concentration of agonist can overcome the inhibition.

**Figure 9. The log(dose)-response curve for irreversible antagonism**

A → D increasing dose of irreversible antagonist
With co-administration of antagonist, increasing dose of agonist does not completely overcome antagonism, as seen in B. Eventually with high enough antagonist concentrations, no amount of agonist can elicit a response, as seen in D.
Effectiveness and Safety

Effectiveness
- ED₅₀ (Effective Dose – 50%): the dose of a drug needed to cause a therapeutic effect in 50% of a test population of subjects

Safety
- LD₅₀ (Lethal Dose – 50%): the dose of a drug needed to cause death in 50% of a test population of subjects (usually rodents)
- TD₅₀ (Toxic Dose – 50%): the dose needed to cause a harmful effect in 50% of a test population of subjects

Therapeutic Indices

Therapeutic Index (TI): TD₅₀/ED₅₀ (see Figure 10)
- reflects the “margin of safety” for a drug – the likelihood of a therapeutic dose causing serious toxicity or death
- the larger the TI, the safer a drug (e.g. warfarin has a narrow TI and requires accurate therapeutic monitoring)
- factors that can change the ED₅₀, LD₅₀ or TD₅₀
  - presence of interacting drugs
  - changes in drug absorption, distribution, metabolism, elimination

Certain Safety Factor (CSF): TD₁/ED₉₉
- CSF>1 translates to a dose effective in at least 99% of the population and toxic in less than 1% of the population.
- unlike TI, CSF does not take into account the shape of the cumulative dose-response curves of the therapeutic and toxic effects

Figure 10. ED₅₀, TD₅₀, and the therapeutic index (TI)

Therapeutic Drug Monitoring (TDM)

- definition: using serum drug concentration data to optimize drug therapy (e.g. dose adjustment, monitor compliance)
  - serum drug samples are usually taken when the drug has reached steady state (e.g. trough level – the lowest level before the next dose)
- TDM can serve to monitor for side effects (e.g. vancomycin trough levels) and for desired effect (e.g. INR when on warfarin therapy)
- TDM is often used for drugs that have:
  - narrow therapeutic index (TI)
  - unpredictable dose-response relationship
  - significant consequences associated with therapeutic failure or toxicity
  - wide inter-patient pharmacokinetic variability

Examples of drugs whose levels need to be monitored: warfarin (via INR levels), digoxin, lithium, anti-epileptics (e.g. phenytoin, carbamazepine), and many others.
Adverse Drug Reactions (ADRs)

Table 3. Comparison of Characteristics of Type A and Type B Reactions

<table>
<thead>
<tr>
<th>Type A</th>
<th>Type B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Predictable extension of drug’s pharmacologic effect</td>
<td>Unpredictable</td>
</tr>
<tr>
<td>Usually dose dependent</td>
<td>Rarely dose dependent</td>
</tr>
<tr>
<td>Low mortality (some exceptions)</td>
<td>High mortality (some exceptions)</td>
</tr>
<tr>
<td>Responds to dose reduction</td>
<td>Responds to drug withdrawal</td>
</tr>
</tbody>
</table>

Type A Drug Reactions

- definition: undesirable normal/augmented responses to the drug (>80% of all ADRs)
- extension of a drug's pharmacological effects (e.g. β-blockers causing bradycardia; acetaminophen causing hepatitis)
- overdose/toxicity: exaggerated but characteristic pharmacological effect from supra-therapeutic dose
- teratogen: drug may produce developmental defects in fetus (not always in a dose-related manner)

Type B Drug Reactions

- definition: reactions unrelated to the known pharmacological actions of the drug
- idiosyncratic: uncharacteristic response to drug, unrelated to pharmacology (e.g. sulfa-containing medications causing toxic epidermal necrolysis)
- allergic/immune-mediated: does not occur on first exposure (up to 7 d), immediate with subsequent exposure, may occur with low doses, often resolves within 3-4 d of discontinuation
- pseudoallergenic: mimics immune-mediated reaction

Type C Drug Reactions

- associated with long-term drug therapy
- effects are well-known and can be anticipated
- i.e. benzodiazepine dependence, analgesic nephropathy

Type D Drug Reactions

- delayed effects
- carcinogenic or teratogenic

Other ADR Categories

- type E (end-of-treatment effects)
- type F (failure of therapy)

Approach to Suspected ADRs

- history and physical examination: signs and symptoms of the reaction (e.g. rash, fever, hepatitis, anaphylaxis), timing, risk factors, detailed medication history including all drugs and timing, dechallenge (response when drug is removed) and rechallenge (response when drug is given again)
- differentiate between drug therapy vs. disease pathophysiology
- treatment: stop the drug, supportive care, symptomatic relief
- resources: check recent literature, Health Canada and FDA; contact the pharmaceutical company; call Poison Control (1-888-268-9017) if overdose or poisoning suspected; check with Motherisk (www.motherisk.org) in cases involving pregnant or breastfeeding women
- Canadian Adverse Drug Reaction Monitoring Program available online for reporting
- report all suspected ADRs that are: 1) unexpected, 2) serious, or 3) reactions to recently marketed drugs (on the market <5 yr) regardless of nature or severity

In Canada, an estimated 1.6% of patients admitted to hospitals experience a serious adverse drug reaction. Furthermore, up to 24% of hospitalizations are drug related, of which 35.5% are adverse drug reactions.
### Variability in Drug Response

- recommended patient dosing is based on clinical research and represents mean values for a select population, but each person may be unique in their dosing requirements
  - the majority (but not all) of the patients will experience the desired therapeutic effect of a drug with minimal ADRs on the recommended dose
  - may need to adjust dosing or alter medication altogether
- possible causes of individual variability in drug response include problems with:
  - intake
    - patient adherence, e.g. hard to follow dosing schedule, unpalatable drug, costly drug
  - pharmacokinetics (review pages CP3-CP7)
    - absorption
      - decreased by vomiting, diarrhea or steatorrhea
      - first pass effect too high due to enzyme induction or too low due to liver disease
      - absorption change due to drug interactions (e.g. calcium carbonate complexes with iron, thyroxine, fluoroquinolones)
    - distribution
      - very high or low percentage body fat, intact or disrupted BBB
      - patient is elderly or a neonate or has liver dysfunction
  - biotransformation and elimination
    - certain genetic polymorphisms or enzymes deficiencies to metabolize drugs (e.g. acetylcholinesterase deficiency, CYP polymorphism)
    - kidney or liver dysfunction or obstruction of bile elimination pathway
  - pharmacodynamics
    - genetic variability in drug response (e.g. malignant hyperthermia due to specific anesthetic agents)
    - disease process that affects drug pharmacodynamics
    - drug tolerance or cross-tolerance

---

### Sulfonamides Containing Medications

- Sulfamethoxazole
- Sulfasalazine
- Dapsone
**Drug Interactions**

- concomitant prescriptions: one drug alters the effect of another by changing its PK fate and/or PD action
- pharmacokinetic interactions involve:
  - absorption: alterations in gastrointestinal pH, gastric emptying, intestinal motility, gut mucosal function
  - biotransformation: alterations in drug metabolizing enzymes
  - excretion: alterations in renal elimination
- pharmacodynamic interactions are drug-induced alterations in the effects of other drugs due to exertion of similar changes to the body’s physiology (additive) or opposing changes (subtractive)
- drug interactions can also involve herbal medications (e.g. St. John’s Wort) and food (e.g. grapefruit)

</table>

**Autonomic Pharmacology**

- most organs are innervated by both sympathetic and parasympathetic nerves; these have opposing effects (see Neurology, Figure 8, N6)
- almost all ANS efferent tracts are divided into preganglionic and postganglionic nerves, which synapse in the autonomic ganglion (see Figure 12)
- sympathetic preganglionic fibers originate in the spinal cord at spinal levels T1-L3, and terminate in one of two ganglia
  1. paravertebral ganglia (i.e. the sympathetic trunk) that lie in a chain close to the vertebral column
  2. pre-vertebral ganglia (i.e. celiac and mesenteric ganglia) that lie within the abdomen
- parasympathetic preganglionic fibers originate in the lower brainstem from cranial nerves III, VII, IX, X, and in the sacral spinal cord at levels S2-S4; they terminate in the ganglionic cells located near or within the target organ
- blood vessels, sweat glands, spleen capsule, adrenals, do NOT have parasympathetic innervation

**Figure 11. Subdivisions of the peripheral nervous system**

**Figure 12. Autonomic nervous system (ANS) efferent tracts**
**Parasympathetic Nervous System (PNS)**

- **acetylcholine (ACh)** is the main neurotransmitter of the parasympathetic nervous system
- **ACh** receptors include
  - **nicotinic (pre-ganglionic) receptors** located in the autonomic ganglia
  - **nicotinic (post-ganglionic) receptors** in the adrenal medulla
  - **muscarnic (only post-ganglionic) receptors**
    - M₁ located in the CNS
    - M₂ receptors located on smooth muscle, cardiac muscle, and glandular epithelium
- **ACh action** is terminated by metabolism in the synaptic cleft by **acetylcholinesterase** and in the plasma by **pseudocholinesterase**
  - e.g. **acetylcholinesterase inhibitors** (donepezil, galantamine, rivastigmine) are used to increase ACh levels in conditions such as myasthenia gravis and Alzheimer’s disease

**Sympathetic Nervous System (SNS)**

- **norepinephrine (NE)** is the major neurotransmitter of the SNS
- **receptors** include
  - β₁: predominately in cardiac tissue
  - β₂: predominately in smooth muscle and glands
  - α₁: predominately on post-synaptic receptors in smooth muscles and glands
  - α₂: predominately on pre-synaptic terminals, where they feed back to inhibit further NE release; also exist as post-synaptic terminals in the brain, uterus, and vascular smooth muscle
- **NE action** is terminated by reuptake by the presynaptic membrane, diffusion from the synaptic cleft and degradation by **monoamine oxidase** (MAO) and **catechol-O-methyl transferase** (COMT)

Introduction to Skin

Skin Anatomy

- **Epidermis**
  - avascular: receives its nutrition from the dermal capillaries
  - derived from keratinocytes with the youngest presenting at the stratum basale (Figure 1A)
  - stratum basale (germinativum): mitotic figures that give rise to keratinocytes
  - stratum spinosum (prickle cells): junctions in this layer (tonofilaments) give the epidermis its strength
  - stratum granulosum: flat cells containing basophilic granules which characterize skin
  - stratum lucidum: comprised of transparent layers of packed dead cells
  - stratum corneum: flat scales of the water-resistant protein keratin

- **Dermis**: comprised of connective tissue divided into two regions (Figure 1B):
  - papillary: contains numerous capillaries that supply nutrients to the dermis and epidermis
  - reticular: provides a strong structure for skin; consists of collagen bundles woven together along with elastic fibres, fibroblasts, and macrophages

- **Subcutaneous tissue** (subdermal)
  - consists primarily of adipose cells, larger caliber vessels, nerves and fascia

Cells in Epidermis

- keratinocytes: located in all layers of the epidermis, except the stratum corneum; connected to each other by desmosomes
- melanocytes: located in the stratum basale; keratinocyte to melanocyte ratio in the basal layer is 10:1; melanocyte number is equal among races
- Langerhans cells: important for immune surveillance
- Merkel cells: involved in touch sensation

Skin Appendages

- epidermal in origin; can extend into the dermis, includes hair, nails, and cutaneous glands

Cutaneous Glands

- **Sebaceous glands**: part of pilosebaceous unit, produces sebum which is secreted into the hair follicle via the sebaceous duct, where it covers the skin surface (protective function)
  - sebum has some antifungal properties
  - these glands cover entire skin surface except palms and soles

- **Apocrine sweat gland**: apocrine duct empties into hair follicle above sebaceous gland
  - found in axillae and perineum
  - likely a vestigial structure, functions in other species to produce scent (e.g. pheromones)

- **Eccrine sweat gland**: not part of pilosebaceous unit
  - found over entire skin surface except lips, nail beds and glans penis
  - important in temperature regulation via secretion of sweat to cool skin surface

Figure 1. Histologic layers of the skin. Epidermal layer is detailed in A

Acronyms

- AAFP: American Association of Family Physicians
- AD: atopic dermatitis
- AK: actinic keratosis
- ASA: acetylsalicylic acid
- ASO: anti-streptolysin O
- BCC: basal cell carcinoma
- BSA: body surface area
- BUN: blood urea nitrogen
- C&S: culture and sensitivity
- CBC: complete blood count
- CNS: central nervous system
- Cr: creatinine
- DLE: discoid lupus erythematosus
- DM: diabetes mellitus
- DVT: deep vein thrombosis
- EM: erythema multiforme
- ESR: erythrocyte sedimentation rate
- Fe: iron
- FTA-ABS: fluorescent treponemal antibody-absorption
- GAS: group A β-hemolytic Streptococcus
- GVHD: graft-versus-host disease
- HHV: human herpes virus
- HPA: hypothyroid-pituitary-adrenal
- HPV: human papilloma virus
- HRT: hormone replacement therapy
- HSV: herpes simplex virus
- HEV: herpes zoster virus
- IFN: interferon
- IVG: intravenous immunoglobulin
- LFT: liver function test
- MDI: monoamine oxidase inhibitor
- MM: malignant melanoma
- MMR: measles/mumps/rubella
- MTP: metatarsal phalangeal
- NB-UVB: narrow band ultraviolet wavelength B
- NCM: neocellular nevus
- ND: Yag: neodymium-doped yttrium aluminium garnet
- MMN: nevus melanocytic nevi
- NMSC: nevus melanoma skin cancers
- NSAID: nonsteroidal anti-inflammatory drug
- OTC: over-the-counter
- PABA: para-aminobenzoic acid
- PASI: Psoriasis Area and Severity Index
- PDD: purified protein derivative
- PUVA: psoralens and long wave ultraviolet radiation
- RA: rheumatoid arthritis
- SCC: squamous cell carcinoma
- SHBG: sex hormone-binding globulin
- SJS: Stevens-Johnson Syndrome
- SL: systemic lupus erythematosus
- SPF: sun protection factor
- SRR: selective serotonin reuptake inhibitor
- SSSS: staphylococcal scalded skin syndrome
- STI: sexually transmitted infection
- TB: tuberculosis
- TEN: toxic epidermal necrolysis
- TMP/SMX: trimethoprin-sulfamethoxazole
- TSH: thyroid stimulating hormone
- UC: ulcerative colitis
- URTI: upper respiratory tract infection
- UV: ultraviolet
- UVA: ultraviolet wavelength A
- UVB: ultraviolet wavelength B
- UVC: ultraviolet wavelength C
- VDRL: venereal disease research laboratory
- VZV: varicella zoster virus
Skin Function

- protection
  - due to continuous recycling and avascularity of epidermis
  - barrier to: UV radiation, mechanical/chemical insults, pathogens and dehydration
- thermal regulation
  - insulation to maintain body temperature in cool environments, via peripheral vasoconstriction, hair and subcutaneous adipose tissue
  - dissipation of heat in warm environments, via increased activity of sweat glands and increased blood flow within dermal vascular networks
- sensation
  - touch, pain, and temperature sensation
- metabolic function
  - vitamin D synthesis
  - energy storage (mainly in the form of triglycerides)

Definitions

Primary Morphological Lesions

Definition
- an initial lesion that has not been altered by trauma or manipulation and has not regressed
- macule: flat lesion <1 cm
- patch: flat lesion ≥1 cm
- papule: elevated, palpable lesion <1 cm
- plaque: elevated, palpable lesion ≥1 cm
- nodule: deep, palpable lesion <1 cm, often dermal or subcutaneous in origin
- tumour: deep, palpable lesion ≥1 cm
- vesicle: fluid-filled lesion <1 cm
- bulla: fluid-filled lesion ≥1 cm
- cyst: an epithelial-lined collection containing semi-solid or fluid material
- pustule: an elevated lesion containing purulent fluid (white, grey, yellow, green)
- erosion: a disruption of the skin involving the epidermis alone; heals without scarring
- ulcer: a disruption of the skin that extends into the dermis or deeper; heals with scarring
- indurated: descriptive term for a lesion that is hard or firm
- scar: replacement fibrosis of dermis and subcutaneous tissue (hypertrophic or atrophic)
- wheal: a special form of papule or plaque that is blanchable and transient, formed by edema in the dermis (e.g. urticaria)

Secondary Morphological Lesions

Definition
- develop during the evolutionary process of skin disease, or created by manipulation, or due to complication of primary lesion (e.g. rubbing, scratching, infection)
- crust: dried fluid (serum, blood, or purulent exudate) originating from a lesion (e.g. impetigo)
- scale: excess keratin (e.g. seborrheic dermatitis)
- lichenification: thickening of the skin and accentuation of normal skin markings (e.g. chronic atopic dermatitis)
- fissure: a linear slit-like cleavage of the skin
- excoriation: a scratch mark
- xerosis: pathologic dryness of skin (xerodermia), conjunctiva (xerophthalmia), or mucous membranes
- atrophy: histological decrease in size and number of cells or tissues, resulting in thinning or depression of the skin

Skin Phototypes (Fitzpatrick)

</tbody>
</table>
Other Morphological Lesions

- **comedones**: collection of sebum and keratin
  - open comedo (blackhead)
  - closed comedo (whitehead; differentiated from pustule)
- **purpura**: extravasation of blood into dermis resulting in hemorrhagic lesions; non-blanchable, 3 mm-1 cm in size
  - petechiae: small pinpoint purpura, <3 mm in size
  - ecchymoses: larger flat purpura, >1 cm in size, aka a “bruise”
- **telangiectasia**: dilated superficial blood vessels; blanchable

Patterns and Distribution

- **acral**: relating to the hands and feet (e.g. hand, foot and mouth disease)
- **annular**: ring-shaped (e.g. granuloma annulare)
- **follicular**: involving hair follicles (e.g. folliculitis)
- **guttate**: lesions following a “drop-like” pattern (e.g. guttate psoriasis)
- **Koebner phenomenon**: aka isomorphic response, appearance of lesions at an injury site (e.g. lichen planus, psoriasis, vitiligo). An isomorphic reaction that develops in areas of trauma (linear exposure, excoriation), after the traumatic event. This can be differentiated from other lesions by arrangement, as Koebner phenomena may not follow dermatomes or the lines of Blaschko
- **morbilliform**: a maculopapular rash resembling measles
- **reticular**: lesions following a net-like pattern (e.g. livedo reticularis)
- **satellite**: lesions scattered outside of primary lesion (e.g. candida diaper dermatitis)
- **serpiginous**: lesions following a snake-like pattern (e.g. cutaneous larva migrans)
- **target/targetoid**: concentric ring lesions, like a dartboard (e.g. EM)
- **other descriptive terms**: discrete, clustered, linear, confluent, dermatitic, indurated

<td>Multiple, hard, variable sized nodules under the scalp, lacks central punctum</td>
<td>Most commonly found at lateral third of eyebrow or midline under nose</td>
<td>Usually solitary, rubbery, translucent; a clear gelatinous viscous fluid may be extruded</td>
<td>1-2 mm superficial, white to yellow subepidermal papules occuring on eyelids, cheeks, and forehead</td>
</tr>
</tbody>
</table>

**Clinical Presentation**

Epithelial cells displaced into dermis, epidermal lining becomes filled with keratin and lipid-rich debris

May be post-traumatic, rarely synechial

**Pathophysiology**

<table>
<thead>
<tr>
<th>Lesion</th>

<td>Usually solitary, rubbery, translucent; a clear gelatinous viscous fluid may be extruded</td>
<td>1-2 mm superficial, white to yellow subepidermal papules occuring on eyelids, cheeks, and forehead</td>
</tr>
</tbody>
</table>

**Clinical Course**

Central punctum may rupture (foul, cheesy odour), creamy colour and produce inflammatory reaction

Increase in size and number over time, especially in pregnancy

**Management**

Excise completely before it becomes infected

Excision

Excision

Drainage ± steroid injection if painful

Compression daily for 6 wk

Excision if bothersome

Incision and expression of contents Laser ablation and electrodessication Multiple facial milia respond to topical retinoid therapy
Fibrous Lesions

DERMATOFIBROMA

Clinical Presentation
- button-like, firm dermal papule or nodule, skin-coloured to red-brown colouring
- majority are asymptomatic but may be pruritic and/or tender
- site: legs > arms > trunk
- dimple sign: lateral compression causes dimpling of the lesion

Pathophysiology
- benign tumour due to fibroblast proliferation in the dermis

Etiology
- unknown; may be associated with history of minor trauma (e.g. shaving or insect bites)
- eruptive dermatofibromata can be associated with SLE

Epidemiology
- adults, F>M

Differential Diagnosis
- dermatofibrosarcoma protruberans, malignant melanoma, Kaposi’s sarcoma, blue nevus

Investigations
- biopsy if diagnosis is uncertain

Management
- no treatment required
- excision or cryosurgery if bothersome

SKIN TAGS

Clinical Presentation
- small (1-10 mm), soft, skin-coloured or darker pedunculated papule, often polypoid
- sites: eyelids, neck, axillae, inframammary, and groin

Pathophysiology
- benign outgrowth of skin

Epidemiology
- middle-aged and elderly, F>M, obese, can increase in size and number during pregnancy

Differential Diagnosis
- pedunculated seborrheic keratosis, compound or dermal melanocytic nevus, neurofibroma, fibroepithelioma of Pinkus (rare variant of BCC)

Management
- excision, electrodesiccation, cryosurgery

Hyperkeratotic Lesions

SEBORRHEIC KERATOSIS

Clinical Presentation
- well-demarcated waxy papule/plaque with classic “stuck on” appearance
- large variety in colour, size and shape
- over time lesions appear more warty, greasy and pigmented
- sites: face, trunk, upper extremities (may occur at any site except palms or soles)

Pathophysiology
- very common benign epithelial tumour

Epidemiology
- unusual <30 yr old
- autosomal dominant inheritance

Differential Diagnosis
- malignant melanoma (lentigo maligna, nodular melanoma), melanocytic nevi, pigmented BCC, solar lentigo, spreading pigmented actinic keratosis
Investigations
• biopsy only if diagnosis uncertain

Management
• none required, for cosmetics only
• cryotherapy, curettage

ACTINIC KERATOSIS (SOLAR KERATOSIS)

Clinical Presentation
• ill-defined, scaly erythematous papules or plaques on a background of sun-damaged skin (solar heliosis)
• sandpaper-like, gritty sensation felt on palpation, often easier to appreciate on palpation rather than inspection
• sites: areas of sun exposure (face, ears, scalp if bald, neck, sun-exposed limbs)

Pathophysiology
• UV radiation damage to keratinocytes from repeated sun exposure (especially UVB)
• risk of transformation of actinic keratosis (AK) to SCC (~1/1000), but higher likelihood if AK is persistent

Epidemiology
• common with increasing age, outdoor occupation, M>F
• skin phototypes I-III (see sidebar, D3), rare in darker skin as melanin is protective

Differential Diagnosis
• SCC in situ, superficial BCC, seborrheic keratosis, cutaneous lupus erythematosus

Investigations
• biopsy lesions that are refractory to treatment

Management
• destructive: cryotherapy, electrodessication and curettage
• pharmacotherapy: 5-fluorouracil cream for 2-3 wk, imiquimod cream for 8-10 wk, photodynamic therapy

KERATOACANTHOMA

Clinical Presentation
• rapidly growing, firm, dome-shaped, erythematous or skin-coloured nodule with central keratin-filled crater, resembling an erupting volcano
• often spontaneously regresses within a year, leaving a scar
• sites: sun-exposed skin

Pathophysiology
• epithelial neoplasm with atypical keratinocytes in epidermis
• low grade variant of SCC

Etiology
• HPV, UV radiation, chemical carcinogens (tar, mineral oil)

Epidemiology
• >50 yr, rare <20 yr

Differential Diagnosis
• treat as SCC until proven otherwise
• hypertrophic solar keratosis, verruca vulgaris

Management
• surgical excision, treated similarly to SCC

CORNs

Clinical Presentation
• firm papule with a central, translucent, cone-shaped, hard keratin core
• painful with direct pressure
• sites: most commonly on dorsolateral fifth toe and dorsal aspects of other toes

Pathophysiology
• localized hyperkeratosis induced by pressure on hands and feet
Epidemiology
• F>M, can be caused by chronic microtrauma

Differential Diagnosis
• tinea pedis, plantar warts

Management
• relieve pressure with padding or alternate footwear, orthotics
• paring, curettage

Keloids

Clinical Presentation
• firm, shiny, skin-coloured or red-bluish papules/nodules that most often arise from cutaneous injury (e.g. piercing, surgical scar, acne), but may appear spontaneously
• extends beyond the margins of the original injury, and may continue to expand in size for years with claw-like extensions
• can be pruritic and painful
• sites: earlobes, shoulders, sternum, scapular area

Pathophysiology
• excessive deposition of randomly organized collagen fibers following trauma to skin
• differentiated from a hypertrophic scar which is confined to the borders of the original injury

Epidemiology
• most common in black patients, followed by those of Asian descent (predilection for darker skin)
• M=F, all age groups

Management
• intralesional corticosteroid injections
• cryotherapy
• silicone compression

Pigmented Lesions

Table 4. Comparison of Pigmented Lesions

<table>
<thead>
<tr>
<th>Ephelides (Freckles)</th>
<th>Solar Lentigo (Liver Spot)</th>
<th>Dermal Melanocytosis (historically known as Mongolian Spot)</th>
<th>Becker’s Nevus</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Clinical Presentation</strong></td>
<td>Small (&lt;5 mm) well-demarcated light brown macules Sites: sun-exposed skin</td>
<td>Well-demarcated brown/black irregular macules Sites: sun-exposed skin</td>
<td>Congenital grey-blue solitary or grouped macules commonly on lumbosacral area</td>
</tr>
<tr>
<td><strong>Pathophysiology</strong></td>
<td>Increased melanin within basal layer keratinocytes secondary to sun exposure</td>
<td>Benign melanocytic proliferation in dermal-epidermal junction due to chronic sun exposure</td>
<td>Ectopic melanocytes in dermis</td>
</tr>
<tr>
<td><strong>Epidemiology</strong></td>
<td>Skin phototypes I and II</td>
<td>Most common in Caucasians &gt;40 yr Skin phototype I-III</td>
<td>99% occurs in Asian and Aboriginal infants M&gt;F Often becomes noticeable at puberty</td>
</tr>
<tr>
<td><strong>Differential Diagnosis</strong></td>
<td>Junctional nevi Juvenile lentigines</td>
<td>Lentigo maligna, seborrhoeic keratosis, pigmented solar keratosis</td>
<td>Ecchymosis</td>
</tr>
<tr>
<td><strong>Clinical Course and Management</strong></td>
<td>No treatment required Multiply and darken with sun exposure, fade in winter Sunscreen may prevent the appearance of new freckles</td>
<td>Laser therapy, shave excisions, cryotherapy</td>
<td>Usually fades in early childhood but may persist into adulthood Hair growth follows onset of pigmentation Cosmetic management (usually too large to remove)</td>
</tr>
</tbody>
</table>

Keloids vs. Hypertrophic Scars
• Keloids: extend beyond margins of original injury with claw-like extensions
• Hypertrophic scars: confined to original margins of injury

DDx of Hyperpigmented Macules
• Purpura (e.g. solar, ASA, anticoagulants, steroids, hemosiderin stain)
• Post-inflammatory
• Melasma
• Melanoma
• Fixed drug eruption
NEVOMELANOCYTIC NEVI (NMN) (see Table 5)

- common mole
- be suspicious of new or changing pigmented lesions (signs of melanoma)
- average number of moles per person: 18-40
- 3 stages of evolution:
  - junctional NMN: macular; arise at dermal-epidermal junction
  - compound NMN: papular; nevus cells invade the papillary dermis
  - dermal NMN: skin coloured papules (no longer hyperpigmented); nevus cells completely migrate into dermis

<td>Melanocytes exclusively in dermis</td>
<td>Same as above</td>
</tr>
<tr>
<td>Dysplastic</td>
<td>Childhood</td>
<td>Variegated macule/papule with irregular indistinct melanocytes in the basal cell layer Risk factors: positive family history</td>
<td>Hyperplasia and proliferation of melanocytes extending beyond dermal compartment of the nevus Often with region of adjacent nests</td>
<td>Follow with colour photographs for changes Excisional biopsy if lesion changing or highly atypical</td>
</tr>
</tbody>
</table>

MELASMA

Clinical Presentation
- dark skin discoloration on sun-exposed areas of face (forehead, upper lip, cheeks, chin)
- usually symmetrical

Pathophysiology
- increase in number and activity of melanocytes
- associated with estrogen and progesterone
- classification determined by depth of hyperpigmentation in the skin (epidermal, dermal, mixed type)
- epidermal pigmentation is most common and can be diagnosed with Wood’s light

Epidemiology
- F>>M
- common in pregnancy (chloasma = ”mask of pregnancy”) and women taking OCP and HRT
- risk factors include sun exposure and dark skin tone
- can occur with mild endocrine disturbances, antiepileptic medications and other photosensitizing drugs
Management

- bleaching cream (hydroquinone), retinoic acid, topical steroids or combination creams
- destructive modalities (chemical peels, laser treatment)
- camouflage make-up
- avoiding sun and using sunscreen are key to preventing melasma
- often fades over several months after stopping hormone treatment or delivering baby

#### HEMANGIOMAS

**Clinical Presentation**
- red or blue subcutaneous mass that is soft/compressible, blanches with pressure; feels like a “bag of worms” when palpated

**Pathophysiology**
- benign vascular tumour
- includes: cavernous hemangioma, capillary/infantile hemangioma, spider hemangioma

#### Table 7. Vascular Tumours

<table>
<thead>
<tr>

<tr>
<td>Epidemiology</td>
<td>Appears shortly after birth; rarely may be congenital</td>
<td>&gt;30 yr old</td>
<td>&lt;30 yr old</td>
<td></td>
</tr>
<tr>
<td>Clinical Course</td>
<td>Appears shortly after birth, increases in size over months, then regresses 50% of lesions resolve spontaneously by 5 yr</td>
<td>Increase in number over time</td>
<td>Lesions do not fade in time Lesions bleed infrequently</td>
<td></td>
</tr>
<tr>
<td>Management</td>
<td>10% require treatment due to functional impairment (visual compromise, airway obstruction, high output cardiac failure) or cosmesis Consider treatment if not gone by school age; Propanolol; systemic corticosteroids; laser treatment; surgery</td>
<td>Electro or laser surgery Systemic corticosteroids and IFN-α may be indicated for rapidly growing lesions</td>
<td>Usually no treatment needed Laser or electrocautery for small lesions Excision of large lesions if necessary</td>
<td>Surgical excision with histologic examination Electrocautery; laser; cryotherapy</td>
</tr>
</tbody>
</table>
VASCULAR MALFORMATIONS

1. Nevus Flammeus (Port-wine stain)

Clinical Presentation
• red to blue macule present at birth that follows a dermatomal distribution, rarely crosses midline
• most common site: nape of neck

Pathophysiology
• congenital vascular malformation of dermal capillaries; rarely associated with Sturge-Weber syndrome (V1, V2 distribution)

Management
• laser or make-up

2. Nevus Simplex (salmon patch)

Clinical Presentation
• pink-red irregular patches
• midline macule on glabella known as "Angel Kiss"; on nuchal region known as "Stork Bites"
• present in 1/3 of newborns
• majority regress spontaneously

Pathophysiology
• congenital dilation of dermal capillaries

Management
• no treatment required

Acneiform Eruptions

Acne Vulgaris/Common Acne

Clinical Presentation
• a common inflammatory pilosebaceous disease categorized with respect to severity
  ▪ Type I: comedonal, sparse, no scarring
  ▪ Type II: comedonal, papular, moderate ± little scarring
  ▪ Type III: comedonal, papular, and pustular, with scarring
  ▪ Type IV: nodulocystic acne, risk of severe scarring
• sites of predilection: face, neck, upper chest, and back

Pathogenesis
• hyperkeratinization, at the follicular ostia (opening), blocks the secretion of sebum (microcomedones)
• androgens stimulate sebaceous glands to produce sebum
• anaerobic diphtheroid Propionibacterium acnes bacteria contains lipase, which converts sebum to free fatty acids and produces pro-inflammatory mediators

Epidemiology
• age of onset in puberty (10-17 yr in females, 14-19 yr in males)
• in prepubertal children consider underlying hormonal abnormality (e.g. late onset congenital adrenal hyperplasia)
• more severe in males than in females
• incidence decreases in adulthood
• genetic predisposition: majority of individuals with cystic acne have parent(s) with history of severe acne

Differential Diagnosis
• folliculitis, keratosis pilaris (upper arms, face, thighs), perioral dermatitis, rosacea

Management
• see Table 8

Acne Myths Debunked
• Eating greasy food and chocolate does not cause or worsen acne
• Blackheads (comedones) are black because of oxidized fatty acids, not dirt
• Acne is not caused by poor hygiene; on the contrary, excessive washing of face can be an aggravator

Acne Exacerbating Factors
• Systemic medications: lithium, phenytoin, steroids, halogens, androgens, iodides, bromides, danazol
• Topical agents: steroids, tars, ointments, oily cosmetics
• Mechanical pressure or occlusion, such as leaning face on hands
• Emotional stress

Intralesional Injections
Intralesional corticosteroid injections are effective in the treatment of individual acne nodules.

A combination of topical retinoids and topical erythromycin or clindamycin is more effective than either agent used alone.
Table 8. Management of Acne

</tr>
<tr>
<td><strong>MODERATE ACNE</strong>: After topical treatments have failed, add oral antibiotics, such as tetracycline (250 mg PO bid to 500 mg bid), or erythromycin (500 mg PO bid). Antibiotics require 3-6 mo of use before assessing efficacy. Consider hormonal therapy, including antiandrogens</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Tetracycline</td>
<td>Inhibits protein synthesis</td>
<td>Use caution with regard to drug interactions: do not use with isotretinoin. Sun sensitivity</td>
</tr>
<tr>
<td>Cyproterone acetate-ethinyl estradiol (Diane-35®)</td>
<td>Cyproterone: potent anti-androgenic, progestogenic and antigonadatrophic activity Ethinyl estradiol: increases level of SHBG, reducing circulating plasma levels of androgens</td>
<td>After 35 yr of age, estrogen/progesterone should only be considered in exceptional circumstances, carefully weighing the risk/benefit ratio with physician guidance</td>
</tr>
<tr>
<td>Spirolactone (source ADA)</td>
<td>Blocks androgen receptors</td>
<td>May cause hyperkalemia at higher doses Black box warning for breast cancer</td>
</tr>
<tr>
<td><strong>SEVERE ACNE</strong>: Consider systemic retinoids after above treatments have failed or if significant scarring present</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Isotretinoin (Accutane®, Clarus®)</td>
<td>Retinoid that inhibits sebaceous gland function and regulates keratinization</td>
<td>See Table 29, D46 for full side effect profile Most adverse effects are temporary and will resolve when the drug is discontinued Baseline lipid profile (risk of hypertriglyceridemia), LFTs and β-hCG before treatment May transiently exacerbate acne before patient sees improvement Drug may be discontinued at 16-20 wk when nodule count has dropped by &gt; 70% A second course may be initiated after 2 mo pm Refractory cases may require multiple courses of isotretinoin</td>
</tr>
</tbody>
</table>

**Perioral Dermatitis**

**Clinical Presentation**
- discrete erythematous micropapules that often become confluent, forming inflammatory plaques on perioral, perinasal and periorbital skin
- commonly symmetrical, rim of sparing around vermillion border of lips
- aggravated by topical glucocorticoids

**Epidemiology**
- 15-40 yr old, occasionally in younger children
- predominantly females

**Differential Diagnosis**
- contact dermatitis, rosacea, acne vulgaris

**Antibiotics are used in inflammatory skin conditions since they also have anti-inflammatory properties (e.g. macrolides in acne). Topical antibiotics may also be used to treat secondary bacterial superinfections (e.g. impetigo).**
Management
- avoid all topical steroids
- topical: metronidazole 0.75% gel or 0.75-1% cream to affected area bid
- systemic: tetracycline family antibiotic (utilized for its anti-inflammatory properties)

Rosacea

Clinical Presentation
- dome-shaped papules ± pustules
- flushing, non-transient erythema and telangiectasia
- distribution: typically on central face including forehead, nose, cheeks and chin (see Figure 3); rarely on scalp, neck and upper body
- characterized by remissions and exacerbations
- exacerbating factors: heat, cold, wind, sun, stress, drinking hot liquids, alcohol, caffeine, spices (triggers of vasodilation)
- all forms of rosacea can progress from mild to moderate to severe
- rarely in longstanding rosacea, signs of thickening, induration and lymphedema in the skin can develop
- phyma: a distinct swelling caused by lymphedema and hypertrophy of subcutaneous tissue, particularly affecting the nose (rhinophyma)
- ocular manifestations: blepharoconjunctivitis, keratitis, iritis

Pathophysiology
- unknown

Epidemiology
- although found in all skin types, highest prevalence in fair-skinned people
- 30-50 yr old; F>M

Differential Diagnosis
- acne vulgaris, seborrheic dermatitis, perioral dermatitis, contact dermatitis

Management
- trigger avoidance is key to long term management
- avoid topical corticosteroids
- make-up to mask erythema
- telangiectasia: treated by physical ablation; electrical hyfrecators, vascular lasers, and intense pulsed light therapies
- phymas: treated by physical ablation or removal; paring, electrosurgery, cryotherapy, laser therapy (CO2, argon, Nd:YAG)
- early diagnosis and prompt treatment are recommended to prevent worsening

Dermatitis (Eczema)

Definition
- inflammation of the skin

Clinical Presentation
- symptoms include pruritus and pain
- acute dermatitis: papules, vesicles
- subacute dermatitis: scaling, crusting
- chronic dermatitis: lichenification, xerosis, fissuring

Figure 3. Rosacea distribution

Guidelines for the Diagnosis of Rosacea
J Am Acad Dermatol 2002;46:584-7
Presence of one or more of the following primary features:
- Flushing (transient erythema)
- Nontransient erythema
- Papules and pustules
- Telangiectasia

May include one or more of the following secondary features:
- Burning or stingning
- Dry appearance
- Edema
- Phymatous changes
- Ocular manifestations
- Peripheral location

Subtypes and Variants of Rosacea and Their Characteristics
N.B. the subtypes can all coexist and can be seen on a spectrum of severity

SUBTYPE
- Erythromatotelangiectatic
  - Flushing, persistent central facial erythema ± telangiectasia
- Papulopustular
  - Persistent central facial papules or pustules or both
- Phymatous
  - Thickening skin, irregular surface nodularities and enlargement
  - Nose most commonly, rarely occurs elsewhere (chin, forehead, cheeks or ears)
- Ocular
  - Foreign body sensation in the eye, burning or stinging, dryness, itching, ocular photosensitivity, blurred vision, telangiectasia of the sclera or other parts of the eye, or periocular edema

VARIANT
- Granulomatous
  - Noninflammatory, hard, brown, yellow, or red cutaneous papules or nodules of uniform size
Asteatotic Dermatitis

Clinical Presentation
- diffuse, mild pruritic dermatitis secondary to dry skin
- very common in elderly, especially in the winter (aka “winter itch”) but starts in the fall
- shins predominate, looks like a “dried river bed”

Management
- skin rehydration with moisturizing routine
- ± mild corticosteroid creams

Atopic Dermatitis

Clinical Presentation
- subacute and chronic eczematous reaction associated with prolonged severe pruritus
- distribution
  - infant (onset at 2-6 mo old): face, scalp, extensor surfaces
  - childhood (>18 mo): flexural surfaces, especially antecubital fossae, popliteal fossae, and neck
  - adult: hands, feet, flexures, wrists, face, forehead, eyelids, neck
- inflammation, lichenification, excoriations are secondary to relentless scratching
- atopic palms: hyperlinearity of the palms (associated with ichthyosis vulgaris)
- associated with
  - keratosis pilaris (hyperkeratosis of hair follicles, “chicken skin”)
  - xerosis
  - occupational hand dryness

Epidemiology
- frequently affects infants, children, and young adults
- almost 15% of children in developed countries under the age of 5 are affected
- associated with personal or family history of atopy (asthma, hay fever, anaphylaxis, eosinophilia)
- polygenic inheritance: one parent >60% chance for child; two parents >80% chance for child
- childhood onset and hereditary forms may be associated with null mutations in the protein filagrin
- the earlier the onset, the more severe and persistent the disease
- long-term condition with 1/3 of patients continuing to show signs of AD into adulthood

Pathophysiology
- a T-cell driven process with epidermal barrier dysfunction

Investigations
- clinical diagnosis
- consider: skin biopsy, immunoglobulin serum levels (often elevated serum IgE level), patch testing, and skin prick tests

Management
- goal: reduce signs and symptoms, prevent or reduce recurrences/flares
- better outcome (e.g. less flare-ups, modified course of disease) if diagnosis made early and treatment plan individualized
- avoid triggers of AD
- enhance barrier function of the skin
  - regular application of moisturizers
  - emollients hydrate the skin and reduce pruritus
  - twice daily application is recommended even in absence of symptoms, especially after bathing or swimming
  - bathing promotes hydration when followed by the application of moisturizers to the skin followed by occlusives (e.g. petroleum jelly)
- anti-inflammatory therapies
  A. topical corticosteroids
    - effective, rapid symptomatic relief of acute flares
    - best applied immediately after bathing
    - control inflammation with a potent topical steroid; a milder one following resolution of acute flare
    - systemic immunosuppression may be needed in severe cases
    - flares may respond to systemic anti-staphylococcal therapy
    - side effects: skin atrophy, purpura, striae, steroid acne, perioral dermatitis, and glaucoma when used around the eyes

Triggers for Atopic Dermatitis
- Irritants (detergents, solvents, clothing, water hardness)
- Contact allergens
- Environmental aeroallergens (dust mites)
- Inappropriate bathing habits (long hot showers)
- Sweating
- Microbes (S. aureus)
- Stress
Clinical Presentation

- cutaneous inflammation caused by an external agent(s)

Figure 5. Atopic dermatitis treatment algorithm

D15 Dermatology

See: Systematic review.

Conclusions:
- Use of the atopy patch test (APT) is controversial.
- There is no gold standard for Aeroallergen provocation, so APT is used without comparison to another method.
- APT findings are not consistent among children with atopic dermatitis.
- APT may be valuable:
  - May provide diagnostic information and may aid clinical decision making regarding the use of IGE-mediated sensitizations

Future research is needed:
- Need standardized provocation and avoidance testing to determine the clinical relevance of obtaining a positive APT result

To ronto Notes 2014

- one of the main ingredients in Polysporin®
**Dyshidrotic Dermatitis**

**Clinical Presentation**
- “tapioca pudding” papulovesicular dermatitis of hands and feet that coalesce into plaques, followed by painful fissuring
- acute stage often very pruritic
- secondary infection common
- lesions heal with desquamation and may lead to chronic lichenification
- sites: palms and soles ± dorsal surfaces of hands and feet

**Pathophysiology**
- NOT caused by hyperhidrosis (excessive sweating)
- emotional stress may precipitate the dermatitis

**Management**
- topical: high potency corticosteroid with plastic cling wrap occlusion to increase penetration
- intralesional triamcinolone injection
- systemic:
  - prednisone in severe cases
  - antibiotics for secondary *S. aureus* infection

**Nummular Dermatitis**

**Clinical Presentation**
- annular, coin-shaped, pruritic, dry, scaly, erythematous plaques, can become lichenified
- often associated with atopic and dyshidrotic dermatitis
- secondary infection common

**Management**
- moisturization
- mid to high potency corticosteroid ointment bid

**Seborrheic Dermatitis**

**Clinical Presentation**
- greasy, erythematous, yellow, scaling, minimally elevated papules and plaques in areas rich in sebaceous glands, can look moist and superficially eroded in flexural regions
- infants: cause of “cradle cap”
- children: may be generalized with flexural and scalp involvement
- adults: diffuse involvement of scalp margin with yellow to white flakes, pruritus, and underlying erythema
- sites: scalp, eyebrows, eyelashes, beard, glabella, post-auricular, over sternum, trunk, body folds, genitalia

**Pathophysiology**
- possible etiologic association with *Malassezia* spp. (yeast)

**Epidemiology**
- common in infants and at puberty
- increased incidence and severity in immunocompromised patients (e.g. HIV)
- in adults, can cause dandruff (pityriasis sicca)

**Management**
- face: ketoconazole (Nizoral®) cream daily or bid + mild steroid cream daily or bid
- scalp: salicylic acid in olive oil or Derma-Smoothe FS® lotion (peanut oil, mineral oil, fluocinolone acetonide 0.01%) to remove dense scales, 2% ketoconazole shampoo (Nizoral®), ciclopirox (Stieprox®) shampoo, selenium sulfide (e.g. Selsun®) or zinc pyrithione (e.g. Head and Shoulders®) shampoo, steroid lotion (e.g. betamethasone valerate 0.1% lotion bid)
**Stasis Dermatitis**

**Clinical Presentation**
- persistent inflammation of the lower legs with erythema, xerosis, scaling, and brownish pigmentation in late stages
- associated with venous insufficiency

**Management**
- compression stockings
- rest and elevate legs (above the level of the heart)
- moisturizer to treat xerosis
- mid-high potency topical corticosteroids to control inflammation

**Complications**
- ulceration (common at medial malleolus), secondary bacterial infections

**Lichen Simplex Chronicus**

**Clinical Presentation**
- chronic dermatitis resulting from continued rubbing/scratching of skin → lichenified skin
- may develop secondarily to another pruritic skin disease

**Management**
- treat pruritus to break the itch-scratch cycle: antihistamines, topical antipruritics
- topical high-potency corticosteroids

**Papulosquamous Diseases**

**Lichen Planus**

**Clinical Presentation**
- acute or chronic inflammation of mucous membranes or skin characterized by violaceous papules, especially on flexural surfaces
- small, polygonal, flat-topped, shiny, violet papules; resolves into hyperpigmented macules
- sites: wrists, ankles, mucous membranes in 60% (mouth, vulva, glans), nails, scalp
- distribution: symmetrical and bilateral
- Wickham's striae: reticulate white-grey lines over surface; pathognomonic
- mucous membrane lesions: lacy, whitish reticular network, milky-white plaques/papules; increased risk of SCC in erosions and ulcers
- nails: longitudinal ridging; dystrophic; pterygium formation
- scalp: scarring alopecia with perifollicular hyperkeratosis
- spontaneously resolves but may last for weeks, months or years (mouth and skin lesions)
- rarely associated with hepatitis C
- Koebner phenomenon
- may be triggered by severe emotional stress

**Management**
- topical corticosteroids with occlusion or intradermal steroid injections
- short courses of oral prednisone (rarely)
- photochemotherapy for generalized or resistant cases
- oral retinoids for erosive lichen planus in mouth
- systemic immunosuppression/modulation e.g. azathioprine, methotrexate, cyclosporine, metronidazole

**Pityriasis Rosea**

**Clinical Presentation**
- acute, self-limiting eruption characterized by red, oval plaques/patches with central scale that does not extend to edge of lesion
- long axis of lesions follows skin tension lines (aka Langer's Lines) parallel to ribs producing “Christmas tree” pattern on back
- varied degree of pruritus
- most start with a “herald” patch which precedes other lesions by 1-2 wk
- sites: trunk, proximal aspects of arms and legs
Etiology
• suspected HHV7

Management
• none required; clears spontaneously in 6-12 wk, reassurance
• topical corticosteroids when post-inflammatory pigmentation is a concern or if patient is uncomfortable
• oral erythromycin or oral acyclovir may expedite healing

Psoriasis

Classification
1. plaque psoriasis  
2. guttate psoriasis  
3. erythrodermic psoriasis  
4. pustular psoriasis  
5. psoriatic arthritis

Differential Diagnosis
• atopic dermatitis, mycosis fungoides (cutaneous T-cell lymphoma), seborrheic dermatitis, tinea

Diagnosis
• usually clinical, biopsy to confirm
• psoriasis area and severity index (PASI)
  ▪ score is based on: percentage of surface area involved and the severity of symptoms (erythema, infiltration, desquamation)

1. PLAQUE PSORIASIS

Clinical Presentation
• chronic and recurrent disease characterized by well-circumscribed erythematous papules/plaques with silvery-white scales
• often worse in winter (lack of sun and humidity)
• Koebner phenomenon
• Auspitz sign: bleeds from minute points when scale is removed
• usually non-pruritic
• exacerbating factors: drugs (lithium, ethanol, chloroquine, β-blockers), stress
• sites: scalp, extensor surfaces of elbows and knees, trunk (especially buttocks), nails, pressure areas

Pathophysiology
• decreased epidermal transit time from stratum basale to stratum corneum
• shortened cell cycle of psoriatic compared to normal skin
• Th1-mediated inflammatory response

Management

*Can also be used to treat psoriatic arthritis

2. GUTTATE PSORIASIS (“DROP-LIKE”)

Clinical Presentation
- discrete, scattered salmon-pink scaling papules
- sites: generalized, sparing palms and soles
- often antecedent streptococcal pharyngitis

Management
- UVB phototherapy, sunlight, lubricants
- penicillin V or erythromycin if Group A β-hemolytic Streptococcus on throat culture

3. ERYTHRODERMIC PSORIASIS

Clinical Presentation
- generalized erythema with fine desquamative scale on surface
- associated symptoms: arthralgia, severe pruritus
- may present in patient with previous mild plaque psoriasis
- aggravating factors: lithium, β-blockers, NSAIDs, antimalarials, phototoxic reaction, infection

Management
- hospitalization, bed rest, IV fluids, monitor fluid and electrolytes
- treat underlying aggravating condition, sun avoidance
- methotrexate, cyclosporine, UV, oral retinoids, biologics

Mechanism of Biologics
- “-mab” = monoclonal antibody
- “-cept” = receptor
4. PUSTULAR PSORIASIS

Clinical Presentation
- sudden onset of erythematous macules and papules which evolve rapidly into pustules, very painful
- can be generalized or localized to palms/soles
- patient usually has history of psoriasis; may occur with sudden withdrawal from steroid therapy

Management
- methotrexate, oral retinoids, biologics

5. PSORIATIC ARTHRITIS

- 5 categories
  - asymmetric oligoarthropathy
  - DIP joint involvement (predominant)
  - rheumatoid pattern (symmetric polyarthropathy)
  - psoriatic arthritis mutilans (most severe form)
  - predominant spondylitis or sacroiliitis
- see Rheumatology RH23

Vesiculobullous Diseases

Bullous Pemphigoid

Clinical Presentation
- chronic autoimmune bullous eruption characterized by pruritic, tense, subepidermal bullae on an erythematous or normal skin base
- sites: flexor aspect of forearms, axillae, medial thighs, groin, abdomen, mouth (33%)

Pathophysiology
- IgG produced against dermal-epidermal basement membrane proteins (hemidesmosomes) leads to subepidermal bullae

Epidemiology
- 60-80 yr old
- there are case reports of association with internal malignancy, but this is exceedingly rare

Investigations
- immunofluorescence shows linear deposition of IgG and C3 along the basement membrane
- anti-basement membrane antibody (IgG) (pemphigoid antibody detectable in serum)

Prognosis
- generalized bullous eruption heals without scarring
- rarely fatal

Management
- prednisone ± steroid-sparing agents (e.g. azathioprine, methotrexate)
- topical potent steroids (clobetasol) may be as effective as systemic steroids
- tetracycline ± nicotinamide is effective for some cases
- dapsone for milder cases

Pemphigus Vulgaris

Clinical Presentation
- autoimmune blistering disease characterized by flaccid, non-pruritic epidermal bullae/vesicles on an erythematous or normal skin base
- may present with erosions and secondary bacterial infection
- sites: mouth (90%), scalp, face, chest, axillae, groin, umbilicus
- Nikolsky’s sign: sliding or rubbing pressure on skin ⇒ separation of epidermis
- Asboe-Hansen sign: pressure applied to bulla causes it to extend laterally

Pathophysiology
- IgG produced against epidermal desmoglein-1 and -3 leads to intraepidermal bullae

Epidemiology
- 40-60 yr old, higher prevalence in Jewish, Mediterranean, Asian populations
- paraneoplastic pemphigus may be associated with thymoma, myasthenia gravis, malignancy, and use of D-penicillamine
**Investigations**
- immunofluorescence: shows IgG and C3 deposition intraepidermally
- circulating serum anti-desmoglein IgG antibodies

**Prognosis and Clinical Course**
- begins with mouth lesions, followed by skin lesions
- first localized (6-12 mo) then generalized
- lesions heal with hyperpigmentation but no scar
- may be fatal unless treated with immunosuppressive agents

**Management**
- prednisone 1-3 mg/kg until no new blisters, then 1-1.5 mg/kg until clear, then taper
- steroid-sparing agents: azathioprine, methotrexate, gold, cyclophosphamide, cyclosporine, intravenous immunoglobulin (IVIG), mycophenolate mofetil, rituximab
- plasmapheresis for acutely high antibody levels

</tbody>
</table>

**Dermatitis Herpetiformis**

**Clinical Presentation**
- grouped papules/vesicles/urticarial wheals on an erythematous base, associated with intense pruritus, burning, stinging
- almost always excoriated, rarely seen as blisters
- lesions grouped, bilaterally symmetrical
- sites: extensor surfaces of elbows/knees, sacrum, buttocks, scalp

**Pathophysiology**
- 90% have HLA B8, DR3, DQWZ
- 90% associated with an often subclinical gluten-sensitive enteropathy (celiac)
- 30% have thyroid disease; increased risk of intestinal lymphoma in untreated comorbid celiac disease; iron/folate deficiency is common

**Epidemiology**
- 20-60 yr old, M:F = 2:1

**Management**
- dapsone for pruritus
- gluten-free diet for life

**Porphyria Cutanea Tarda**

**Clinical Presentation**
- tense vesicles/bullae in photoexposed areas subjected to trauma
- facial hypertrichosis, brown hypermelanosis vesicles, and bullae in photodistribution (dorsum of hands and feet)
- sites: light-exposed areas subjected to trauma, dorsum of hands and feet, nose, and upper trunk

**Pathophysiology**
- autosomal dominant or sporadic skin disorder associated with the presence of excess heme precursors
- associated with hemochromatosis, alcohol abuse, DM, drugs (estrogen therapy, NSAIDs), HIV, hepatitis C, increased iron indices

**Epidemiology**
- 30-40 yr old, M>F
**Investigations**
- urine + 5% HCl shows orange-red fluorescence under Wood's lamp (UV rays)
- 24 hour urine for uroporphyrins (elevated)
- stool contains elevated coproporphyrins
- immunofluorescence shows IgE at dermal-epidermal junctions

**Management**
- discontinue aggravating substances (alcohol, estrogen therapy)
- phlebotomy to decrease body iron load
- low dose hydroxychloroquine

---

**Drug Hypersensitivity Syndrome**
- fever followed by symmetrical bright red exanthematous eruption that may lead to internal organ involvement (hepatitis, arthralgia, nephritis, pneumonitis, lymphadenopathy, hematologic abnormalities, thyroid abnormalities)
- classically occurs approximately 7-10 d after first exposure to the drug
- may be elevated incidence of similar reactions in siblings
- most common causes: sulfonamides, allopurinol, and anticonvulsants (phenytoin, phenobarbital, carbamazepine, lamotrigine)
- 10% mortality if severe, undiagnosed, and untreated

**Erythema Multiforme (EM), Stevens-Johnson Syndrome (SJS), Toxic Epidermal Necrolysis (TEN)**
- disorders with varying presence of characteristic skin lesions, blistering and mucous membrane involvement

### Table 15. Comparison of Erythema Multiforme, Stevens-Johnson Syndrome, Toxic Epidermal Necrolysis

<td>As for Stevens-Johnson syndrome Admit to burn unit Debride frankly necrotic tissue Consider IVIG vs. cyclosporine</td>
</tr>
</tbody>
</table>
Exanthematous Eruptions (Maculopapular Eruptions/Morbilliform)

- symmetrical, widespread, erythematous patches or plaques ± scales
- the "classic" and most common adverse drug reaction
- often starts on trunk
- may progress to generalized exfoliative dermatitis especially if the drug is continued
- most common causes: penicillin, sulfonamides, phenytoin

Fixed Drug Eruptions

- sharply demarcated erythematous oval patches on the skin or mucous membranes
  - sites: face, mucosa, genitalia, acral
  - reoccurs in same location upon subsequent exposure to the drug (fixed location)
- most common causes: antimicrobials (tetracycline, sulfonamides), anti-inflammatories, psychoactive agents (barbiturates), phenolphthalein

Photosensitivity Eruptions

- phototoxic reaction: "an exaggerated sunburn" confined to sun-exposed areas
- photoallergic reaction: an eczematous eruption that may spread to areas not exposed to light
- most common causes: chlorpromazine, doxycycline, thiazide diuretics, procainamide

Serum Sickness-Like Reaction

- a symmetric drug eruption resulting in fever, arthralgia, lymphadenopathy, and skin rash (urticaria)
- usually appears 5-10 d after drug exposure
- most common causes: cefaclor in kids; buproprion (Zyban®, Wellbutrin®) in adults

Heritable Disorders

Ichthyosis Vulgaris

Clinical Presentation
- generalized hyperkeratosis leading to dry skin
- genetic deficiency in filaggrin protein
- “fish-scale” appearance especially on extremities with sparing of flexural creases, palms and soles

Pathophysiology
- abnormal retention of keratinocytes (hyperkeratosis)
- scaling without inflammation

Epidemiology
- 1:300 incidence
- autosomal dominant inheritance
- associated with atopic dermatitis and keratosis pilaris

Management
- immersion in bath and oils
- emollient or humectant creams, and creams or oils containing urea or α- or β-hydroxy acids
**Neurofibromatosis (Type I; von Recklinghausen’s Disease)**

**Clinical Presentation**
- diagnostic criteria includes 2 or more of the following:
  1. more than 5 café-au-lait patches >1.5 cm in an adult or more than 5 café-au-lait macules >0.5 cm in a child under age 5
  2. axillary or inguinal freckling
  3. iris hamartomas (Lisch nodules)
  4. optic gliomas
  5. neurofibromas
  6. distinctive bony lesion (sphenoid wing dysplasia or thinning of long bone cortex)
  7. first degree relative with neurofibromatosis type I
- associated with pheochromocytoma, astrocytoma, bilateral acoustic neuromas, bone cysts, scoliosis, precocious puberty, developmental delay, and renal artery stenosis
- skin lesions less prominent in neurofibromatosis Type II (see Pediatrics, P91)

**Pathophysiology**
- autosomal dominant disorder with excessive and abnormal proliferation of neural crest elements (Schwann cells, melanocytes), high incidence of spontaneous mutation
- linked to absence of neurofibromin (a tumour suppressor gene)

**Epidemiology**
- incidence 1:3,000

**Management**
- watch for brain tumors such as astrocytoma
- excise suspicious or painful lesions
- see Pediatrics, P92

---

**Vitiligo**

**Clinical Presentation**
- primary pigmentary disorder characterized by depigmentation
- acquired destruction of melanocytes characterized by sharply margined white patches
- associated with streaks of depigmented hair, chorioretinitis
- sites: extensor surfaces and periorificial areas (mouth, eyes, anus, genitalia)
- Koebner phenomenon, may be precipitated by trauma

**Pathophysiology**
- acquired autoimmune destruction of melanocytes

**Epidemiology**
- 1% incidence, polygenic
- 30% with positive family history

**Investigations**
- rule out associated autoimmune diseases: thyroid disease, pernicious anemia, Addison’s disease, Type I DM
- Wood’s lamp to detect lesions: illuminates UV light onto skin to detect patches of amelanosis

**Management**
- sun avoidance and protection
- topical immunomodulator (i.e. tacrolimus, pimecrolimus) or a topical steroid
- PUVA or Narrow band UVB
- make-up
- “bleaching” normal pigmented areas (i.e. monobenzyl ether of hydroquinone 20%) if widespread loss of pigmentation

---

**Interventions for Vitiligo**
Cochrane DB Syst Rev 2010;1:CD003263

**Study:** Systematic review of randomized controlled trials.

**Patients:** 3139 participants with vitiligo.

**Intervention:** Topical treatments, light therapies, oral treatments, surgical methods, and psychological therapies

**Outcome:** >75% repigmentation, adverse effects

**Results:** Moderate evidence exists for the use of topical corticosteroids to induce repigmentation. However, adverse effects are observed with long-term use. Topical use of non-steroidal immunomodulators (i.e. tacrolimus), especially in combination with light therapies, has also been shown to induce repigmentation. However, long-term use may theoretically increase the risk for skin cancer. In general, combination therapy including some form of light therapy had the most significant improvement. Sustained repigmentation (>2 yr) has not been reported and thus results should be treated with caution.
Infections

Bacterial Infections

- often involve the epidermis, dermis, hair follicles or periungual region ± systemic

EPIDERMIS

IMPETIGO

Clinical Presentation
- acute purulent infection which appears vesicular; progresses to golden yellow “honey-crusted” lesions surrounded by erythema
- can present with bullae
- sites: commonly face, arms, legs and buttocks

Etiology
- GAS, S. aureus, or both

Epidemiology
- preschool and young adults living in crowded conditions, poor hygiene, neglected minor trauma

Differential Diagnosis
- infected eczema, HSV, Varicella virus

Investigations
- Gram stain and culture of lesion fluid or biopsy

Management
- remove crusts, use saline compresses and topical antiseptic soaks bid
- topical antibacterials such as 2% mupirocin or fusidic acid (Canada only) tid; continue for 7-10 d after resolution
- systemic antibiotics such as cloxacillin or cephalexin for 7-10 d

DERMIS

<td>Antiseptic (Hibiclens®) Topical antibacterial (fusidic acid, mupirocin, or erythromycin) Oral cloxacillin for 7-10 d</td>
<td>Incise and drain large carbuncles to relieve pressure and pain If afebrile: hot wet packs, topical antibiotic If febrile/cellulitis: culture blood and aspirate pustules (Gram stain and C&amp;S) Cloxacillin for 1-2 wk (especially for lesions near external auditory canal/rose, with surrounding cellulitis, and not responsive to topical therapy)</td>
<td>Same as for furuncles</td>
</tr>
</tbody>
</table>

### Dermatophytoses

#### Clinical Presentation
- infection of skin, hair and nails caused by dermatophytes (fungi that live within the epidermal keratin or hair follicle and do not penetrate into deeper structures)

#### Pathophysiology
- digestion of keratin by dermatophytes results in scaly skin, broken hairs, crumbling nails/onycholysis

#### Etiology
- *Trichophyton, Microsporum, Epidermophyton* species (*Pityrosporum* is a superficial yeast and not a dermatophyte)

#### Investigations
- skin scrapings, hair, and/or nail clippings analyzed with potassium hydroxide (KOH) prep to look for hyphae and mycelia

#### Management
- topicals as first line agents for tinea corporis/cruris and tinea pedis (interdigital type):
  - e.g. clotrimazole or terbinafine cream applied bid, until one week after complete resolution of lesions
- oral therapy is indicated for onychomycosis or tinea capitis:
  - e.g. terbinafine (Lamisil® – liver toxicity, CYP 2D6 inhibitor) or itraconazole (Sporanox® – CYP 3A4 inhibitor, liver toxicity)

<td>Tinea Corporis (Ringworm)</td>
<td>Pruritic, scaly, round/oval plaque with active erythematous margin and central clearing Site: trunk, limbs, face</td>
<td>Granuloma annulare, pityriasis rosea, psoriasis, seborrheic dermatitis</td>
<td>Microscopic examinations of KOH prep of scales shows hyphae Culture of scales</td>
<td>Topicals: 1% clotrimazole, 2% ketoconazole 2% miconazole, terbinafine or ciclopirox olamine cream bid for 2-4 wk Oral terbinafine, or itraconazole, or fluconazole, or ketoconazole if extensive</td>
</tr>
</tbody>
</table>
### Parasitic Infections

#### SCABIES

**Clinical Presentation**
- A transmissible parasitic skin infection due to *Sarcoptes scabiei*, a mite, characterized by superficial burrows, intense pruritus (especially nocturnal), and secondary infection
- Primary lesion: superficial linear burrows; inflammatory papules and nodules in the axilla and groin
- Secondary lesion: small urticarial crusted papules, eczematous plaques, excoriations
- Sites: axillae, groin, buttocks, hands/feet (especially web spaces), sparing of head and neck (except in infants)

**Pathogenesis**
- Scabies mite remains alive 2-3 d on clothing/sheets
- Incubation of 1 mo, then pruritus begins
- Re-infection followed by hypersensitivity in 24 h

**Etiology**
- *Sarcoptes scabiei*
- Risk factors: sexual promiscuity, crowding, poverty, nosocomial, immunocompromised

**Differential Diagnosis**
- Asteatotic eczema, dermatitis herpetiformis, lichen simplex chronicus (neurodermatitis)

**Investigations**
- Microscopic examination of root and content of burrow and mineral oil mount for mite, eggs, feces

**Management**
- Bathe, then apply permethrin 5% cream (i.e. Nix®) from neck down to soles of feet (must be left on for 8-14 h and requires second treatment 7 d after first treatment)
- Change underwear and linens; wash with detergent in hot water cycle then machine dry
- Treat family and close contacts
- Pruritus may persist for 2-3 wk after effective treatment due to prolonged hypersensitivity reaction
- Mid potency topical steroids and antihistamines for symptom management
LICE (Pediculosis)

Clinical Presentation
- Intensely pruritic red excoriations, morbilliform rash, caused by louse (a parasite)
- Scalp lice: nits (i.e., louse eggs) on hairs
  - Red excoriated skin with secondary bacterial infection, lymphadenopathy
- Pubic lice: nits on hairs
  - Excoriations
- Body lice: nits and lice in seams of clothing
  - Excoriations and secondary infection mainly on shoulders, belt-line and buttocks

Differential Diagnosis
- Bacterial infection of scalp, seborrheic dermatitis

Management
- Permethrin 1% (Nix® cream rinse) (ovicidal) or permethrin 1% (RC & Cor®, Kwellada-P® shampoo)
- Comb hair with fine-toothed comb using dilute vinegar solution to remove nits
- Repeat in 7 d after first treatment
- Shave hair if feasible, change clothing and linens; wash with detergent in hot water cycle then machine dry

Bed bugs (Hemiptera)

Clinical Presentation
- Burning wheals, turning to firm papules, often in groups of three – “breakfast, lunch and dinner” in areas with easy access (face, neck, arms, legs, hands)

Etiology
- Caused by Cimex lectularius, a small insect that feeds mainly at night
- During day bedbugs hide in crevices in walls and furniture

Differential Diagnosis
- Dermatitis herpetiformis, drug eruptions, ecthyma, other insect bites, scabies

Management
- Professional fumigation of home
- Topical steroids and oral H1-antagonists for symptomatic relief
- Definitive treatment is removal of clutter in home and application of insecticides to walls and furniture

Viral Infections

Herpes Simplex

Clinical Presentation
- Herpetiform (i.e., grouped) vesicles on an erythematous base on skin or mucous membranes
- Transmitted via contact with erupted vesicles or via asymptomatic viral shedding
- Primary
  - Children and young adults
  - Usually asymptomatic; may have high fever, regional lymphadenopathy, malaise
  - Followed by antibody formation and latency of virus in dorsal nerve root ganglion
- Secondary
  - Recurrent form seen in adults; much more common than primary
  - Prodrome: tingling, pruritus, pain
  - Triggers for recurrence: fever, excess sun exposure, physical trauma, menstruation, emotional stress, URTI
- Potential complications
  - Dendritic corneal ulcer
  - EM
  - Herpes simplex encephalitis (infants at risk)
  - HSV infection on atopic dermatitis causing Kaposi’s varicelliform eruption (eczema herpeticum)
- Two biologically and immunologically different subtypes: HSV-1 and HSV-2
HSV-1
- typically “cold sores” (grouped vesicles at the mucocutaneous junction which quickly burst)
- recurrent on face, lips and hard palate, but NOT on soft, non-keratinized mucous membranes (unlike aphthous ulcers)

Management
- treat during prodrome to prevent vesicle formation
- topical antiviral (Zovirax®) cream, apply 5-6x/d x 4-7 d for facial/genital lesions
- oral antivirals are far more effective and have an easier dosing schedule

HSV-2
- sexually transmitted; incubation 2-20 d
- gingivostomatitis: entire buccal mucosa involved with erythema and edema of gingiva
- vulvovaginitis: edematous, erythematous, extremely tender, profuse vaginal discharge
- urethritis: watery discharge in males
- recurrent on vulva, vagina, penis for 5-7 d
- diagnosis
  - negative dark field, negative serology for syphilis, negative bacterial cultures
  - Tzanck smear with Giemsa stain shows multinucleated giant epithelial cells
  - tissue culture and electron microscopy of vesicular fluid
  - skin biopsy
  - antibody titres increase one week after primary infection only (no increase with recurrent lesions)
- ddx of genital ulcers: Candida balanitis, chancroid, syphilitic chancres

Management
- rupture vesicle with sterile needle if you wish to culture it
- wet dressing with aluminum subacetate solution, Burow’s compression, or betadine solution
- 1st episode: acyclovir 200 mg PO 5 times a day x 10 d
  - maintenance: acyclovir 400 mg PO bid
- famciclovir or valacyclovir may be substituted and have better enteric absorption and less frequent dosing
- in case of herpes genitalis, look for and treat any other sexually-transmitted infections
- for active lesions in pregnancy, see Obstetrics, OB21

HERPES ZOSTER (SHINGLES)

Clinical Presentation
- unilateral dermatomal eruption occurring 3-5 d after pain and paresthesia of that dermatome
- vesicles, bullae, and pustules on an erythematous, edematous base
- lesions may become eroded/ulcerated and last days – weeks
- pain is pre-herpetic, synchronous with rash, or post-herpetic
- severe post-herpetic neuralgia often occurs in elderly
- Hutchinson’s sign: involvement of tip of nose suggests eye involvement
- distribution: thoracic (50%), trigeminal (10-20%), cervical (10-20%); disseminated in HIV

Etiology
- caused by reactivation of VZV
- risk factors: immunosuppression, old age, occasionally associated with hematologic malignancy

Differential Diagnosis
- before thoracic skin lesions occur, must consider other causes of chest pain
- contact dermatitis, localized bacterial infection, zosteriform HSV (more pathogenic for the eyes than VZV)

Management
- compress with normal saline, Burow’s, or betadine solution
- analgesics (NSAIDs, amitriptyline)
- famciclovir or valacyclovir or acyclovir for 7 d; must initiate within 72 h to be of benefit
- gabapentin 300-600 mg PO tid for post-herpetic neuralgia

MOLLUSCUM CONTAGIOSUM

Clinical Presentation
- discrete dome-shaped and umbilicated pearly, white papules caused by DNA Pox virus
  - Molluscum contagiosum virus (MCV)
- sites: eyelids, beard (likely spread by shaving), neck, axillae, trunk, perineum, buttocks

Etiology
- MCV is spread via direct contact, auto-inoculation, sexual contact
- common in children and sexually active young adults (giant molluscum and severe cases can be seen in the setting of HIV)
Management
- topical cantharidin (a vesicant)
- cryotherapy
- curettage
- Aldara™ (imiquimod): immune modulator that produces a cytokine inflammation

**WARTS (VERRUCA VULGARIS) [HUMAN PAPILLOMAVIRUS (HPV) INFECTIONS]**

</table>

*Avoid in pregnancy

- other viruses associated with skin changes, e.g. measles, roseola, fifth disease, etc.
- see Pediatric Exanthems, D40

**Treatment for Skin Warts**

**First Line Therapies**
- Salicylic acid preparations (patches, solutions, creams, ointments)
- Cryotherapy
- Topical cantharidin

**Second Line Therapies**
- Topical imiquimod
- Topical 5-Fluorouracil
- Topical tretinoin
- Podophyllotoxin

**Third Line Therapies**
- Curettage
- Caution
- Surgery
- Laser
- Oral cimetidine (particularly children)
- Topical 5-Fluorouracil
- Topical tretinoin (flat warts)
- Localized heat therapy
- Intralesional bleomycin (plantar warts)

**Treatment for Anogenital Warts**

**First line therapies**
- Imiquimod cream
- Podophyllotoxin (solution, cream, or gel)
- Cryotherapy

**Second line therapies**
- Trichloroacetic acid
- Topical 5-Fluorouracil
- Topical tretinoin
- Electrodesiccation
- Surgical excision (with cold steel or scissors)
- CO₂ laser
Yeast Infections

CANDIDIASIS

Candidal Paronychia
• painful red swellings of periungual skin
• management: topical agents not as effective; oral antifungals recommended

Candidal Intertrigo
• macerated/eroded erythematous patches that may be covered with papules and pustules, located in intertriginous areas often under breast, groin, or interdigitally
• peripheral “satellite” pustules
• predisposing factors: obesity, diabetes, systemic antibiotics, immunosuppression, malignancy
• starts as non-infectious maceration from heat, moisture and friction
• management: keep area dry, miconazole, ketoconazole/clotrimazole cream bid until rash clears

PITYRIASIS (TINEA) VERSICOLOR

Clinical Presentation
• chronic asymptomatic superficial fungal infection with brown/white scaling macules
• affected skin darker than surrounding skin in winter, lighter in summer (does not tan)
• sites: upper trunk most common

Pathophysiology
• microbe produces carboxylic acid → inflammatory reaction inhibiting melanin synthesis yielding variable pigmentation
• affinity for sebaceous glands; require fatty acids to survive

Etiology
• Pityrosporum ovale (Malassezia furfur)
• also associated with folliculitis and seborrheic dermatitis
• predisposing factors: summer, tropical climates, Cushing's syndrome, prolonged corticosteroid use

Investigations
• microscopic examination, KOH prep of scales for hyphae and spores

Management
• ketoconazole shampoo or cream PO daily for 7 d if more extensive
• topical terbinafine or ciclopirox olamine
• systemic fluconazole or itraconazole for 7 d

Sexually Transmitted Infections

SYPHILIS

Clinical Presentation
• characterized initially by a painless ulcer (chancre)
• following inoculation, systemic infection with secondary and tertiary stages

Etiology
• Treponema pallidum
• transmitted sexually, congenitally, or rarely by transfusion

Natural History of Untreated Syphilis
• Inoculation
• Primary syphilis (10-90 d after infection)
• Secondary syphilis (simultaneous to primary syphilis or up to 6 mo after healing of primary lesion)
• Latent syphilis
• Tertiary syphilis (2-20 yr)

Latent Syphilis
70% of untreated patients will remain in this stage for the rest of their lives and are immune to new primary infection.
Table 21. Stages of Syphilis

</thead>
</table>

GONOCOCCEMIA

Clinical Presentation
- disseminated gonococcal infection
- hemorrhagic, tender, pustules on a purpuric/petechial background
- sites: distal aspects of extremities
- associated with fever, arthritis, urethritis, proctitis, pharyngitis and tenosynovitis
- neonatal conjunctivitis if infected via birth canal

Etiology
- Neisseria gonorrhoeae

Management
- notify Public Health authorities
- screen for other sexually transmitted infections (STIs)
- cefixime 400 mg PO (drug of choice) or ceftriaxone 125 mg IM

HSV
- see Viral Infections, D29

HPV
- see Viral Infections, D30

Pre-Malignant Skin Conditions

Actinic Keratosis (Solar Keratosis)

Clinical Presentation
- ill-defined, scaly erythematous papules or plaques on a background of sun-damaged skin (solar heliosis)
- sandpaper-like, gritty sensation felt on palpation, often easier to appreciate on palpation rather than inspection
- sites: areas of sun exposure (face, ears, scalp if bald, neck, sun-exposed limbs)

Pathophysiology
- UV radiation damage to keratinocytes from repeated sun exposure (especially UVB)
- risk of transformation of actinic keratosis (AK) to SCC (~1/1000), but higher likelihood if AK is persistent

Types of Actinic Keratosis (AK)
- Erythematous: typical AK lesion
- Hypertrophic: thicker, rough papule/plaque
- Cutaneous horn: firm hyperkeratotic outgrowth
- Actinic cheilitis: confluent AKs on the lip
- Pigmented: flat, tan-brown, scaly plaque
- Spreading pigmented
- Proliferative
- Conjunctival: pinguecula, pterygium
Epidemiology
- common with increasing age, outdoor occupation, M>F
- skin phototypes I-III (see sidebar, D3), rare in darker skin as melanin is protective

Differential Diagnosis
- SCC in situ, superficial BCC, seborrheic keratosis, cutaneous lupus erythematosus

Investigations
- biopsy lesions that are refractory to treatment

Management
- destructive: cryotherapy, electrodessication and curettage
- pharmacotherapy: 5-fluorouracil cream for 2-3 wk, imiquimod cream for 8-10 wk, photodynamic therapy
- excision

Leukoplakia

Clinical Presentation
- a morphologic term describing homogenous or speckled white plaques with sharply demarcated borders
- sites: oropharynx, most often floor of the mouth, soft palate, and ventral/lateral surfaces of the tongue

Pathophysiology
- precancerous or premalignant condition
- oral form is strongly associated with tobacco use and alcohol consumption

Epidemiology
- 1-5% prevalence in adult population after 30 yr of age; peak at age 50
- M>F, fair-skinned
- most common oral mucosal premalignant lesion

Differential Diagnosis
- lichen planus, oral hairy leukoplakia

Investigations
- biopsy is mandatory because it is premalignant

Management
- low risk sites on buccal/labial mucosal or hard palate: eliminate carcinogenic habits, follow-up
- moderate/dysplastic lesions: excision, cryotherapy

Malignant Skin Tumours

Non-Melanoma Skin Cancers

BASAL CELL CARCINOMA (BCC)

Subtypes
- noduloulcerative (typical)
  - skin-coloured papule/nodule with rolled, translucent ("pearly") telangiectatic border and depressed/eroded/ulcerated centre
- pigmented variant
  - flecks of pigment in translucent lesion with surface telangiectasia
  - may mimic malignant melanoma
- superficial variant
  - flat, tan to red-brown plaque, often with scaly, pearly border and fine telangiectasia at margin
  - least aggressive subtype
- sclerosing (morphaform) variant
  - flesh/yellowish-coloured, shiny papule/plaque with indistinct borders, indurated
Pathophysiology
- malignant proliferation of basal keratinocytes of the epidermis
  - low grade cutaneous malignancy, locally aggressive (primarily tangential growth), rarely metastatic
  - usually due to UVB light exposure, therefore >80% on face
  - may also occur in previous scars, radiation, trauma, arsenic exposure, or genetic predisposition (Gorlin syndrome)

Epidemiology
- most common malignancy in humans
- 75% of all malignant skin tumours >40 yr, increased prevalence in the elderly
- M>F, skin phototypes I and II, chronic cumulative sun exposure

Differential Diagnosis
- benign: sebaceous hyperplasia, intradermal melanocytic nevus, dermatofibroma
- malignant: nodular malignant melanoma, SCC

Management
- imiquimod 5% cream (Aldara®) or cryotherapy is indicated for superficial BCCs on the trunk
- shave excision + electrodessication and curettage for most types of BCCs, not including morpheiform
- Mohs surgery: microscopically controlled, minimally invasive, stepwise excision for lesions on the face or in areas that are difficult to reconstruct
- radiotherapy used in advanced cases of BCC where surgical intervention is not an option
- life-long follow-up
- 95% cure rate if lesion <2 cm in diameter or if treated early

SQUAMOUS CELL CARCINOMA (SCC)

Clinical Presentation
- indurated erythematous nodule/plaque with surface scale/crust ± ulceration
- more rapid enlargement than BCC
- sites: face, ears, scalp, forearms, dorsum of hands

Pathophysiology
- malignant neoplasm of keratinocytes (primarily vertical growth)
- predisposing factors include: UV radiation, PUVA, ionizing radiation therapy/exposure, chemical carcinogens (such as arsenic, tar and nitrogen mustards), HPV 16, 18, immunosuppression
- may occur in previous scar (SCC more commonly than BCC)

Epidemiology
- second most common type of cutaneous neoplasm
- primarily on sun-exposed skin in the elderly, M>F, skin phototypes I and II, chronic sun exposure
- in organ transplant recipients SCC is most common cutaneous malignancy, with increased mortality as compared to non-immunocompromised population

Differential Diagnosis
- benign: nummular eczema, psoriasis, irritated seborrheic keratosis
- malignant: keratoacanthoma, Bowen's disease, BCC

Management
- surgical excision with primary closure, skin flaps or grafting
- Mohs surgery
- lifelong follow-up (more aggressive treatment than BCC)

Prognosis
- good prognostic factors: early treatment, negative margins, and small size of lesion
- SCCs that arise from actinic keratosis metastasize less frequently (~1%) than other SCCs (e.g. arising de novo in old burns) (2-5% of cases)
- overall control is 75% over 5 yr, 5-10% metastasize
OTHER FORMS OF SQUAMOUS CELL CARCINOMA (SCC)

BOWEN’S DISEASE (SQUAMOUS CELL CARCINOMA IN SITU)

Clinical Presentation
• erythematous plaque with a sharply demarcated red and scaly border
• often 1-3 cm in diameter and found on the skin and mucous membranes
• evolves to SCC in 10-20% of cutaneous lesions and >20% of mucosal lesions

Management
• same as for BCC
• biopsy required for diagnosis
• topical 5-fluorouracil (Efudex®) or imiquimod (Aldara®) used if extensive and as a tool to identify margins of poorly defined tumours
• cryosurgery
• shave excision with electrodessication and curettage

KERATOACANTHOMA

Clinical Presentation
• rapidly growing, firm, dome-shaped, erythematous or skin-coloured nodule with central keratin-filled crater, resembling an erupting volcano
• may spontaneously regress within a year, leaving a scar
• sites: sun-exposed skin

Pathophysiology
• epithelial neoplasm with atypical keratinocytes in epidermis
• low grade variant of SCC

Etiology
• HPV, UV radiation, chemical carcinogens (tar, mineral oil)

Epidemiology
• >50 yr, rare <20 yr

Differential Diagnosis
• treat as SCC until proven otherwise
• hypertrophic solar keratosis, verruca vulgaris

Management
• surgical excision, treated similarly to SCC

Malignant Melanoma (MM)

Clinical Presentation
• malignant characteristics of a mole: see mnemonic “ABCDE”
• sites: skin, mucous membranes, eyes, CNS

Clinical Subtypes of Malignant Melanoma
• lentigo maligna
  • malignant melanoma in situ (normal and malignant melanocytes confined to the epidermis)
  • 2-6 cm, tan/brown/black uniformly flat macule or patch with irregular borders
  • lesion grows radially and produces complex colours
  • often seen in the elderly
  • 10% evolve to lentigo maligna melanoma
• lentigo maligna melanoma (15% of all melanomas)
  • malignant melanocytes invading into the dermis
  • associated with pre-existing solar lentigo, not pre-existing nevi
  • flat, brown, stain-like, gradually enlarging with loss of skin surface markings
  • with time, colour changes from uniform brown to dark brown with black and blue
  • found on all skin surfaces, especially those often exposed to sun, such as the face and hands
• superficial spreading melanoma (60-70% of all melanomas)
  • atypical melanocytes initially spread laterally in epidermis then invade the dermis
  • irregular, indurated, enlarging plaques with red/white/blue discolouration, focal papules or nodules
  • ulcerate and bleed with growth

Does this Patient have a Mole or Melanoma?

ABCDE checklist

A  symmetry
B  border (irregular and/or indistinct)
C  colour (varied)
D  diameter (increasing or > 6 mm)
E  enlargement, elevation, evolution (i.e., change in colour, size or shape)

Sensitivity 92% (CI 82-98%)
Specificity 100% (CI 54-100%)
JAMA 1998;279:696-701
• nodular melanoma (30% of all melanomas)
  ▪ atypical melanocytes that initially grow vertically with little lateral spread
  ▪ uniformly ulcerated, blue-black, and sharply delineated plaque or nodule
  ▪ rapidly fatal
  ▪ may be pink or have no colour at all, this is called an amelanotic melanoma
  ▪ “EFG” Elevated, Firm, Growing

• acro lentiginous melanoma (5% of all melanomas)
  ▪ ill-defined dark brown, blue-black macule
  ▪ palmar, plantar, subungual skin
  ▪ melanomas on mucous membranes have poor prognosis

Pathophysiology
• malignant neoplasm of pigment forming cells (melanocytes and nevus cells)

Epidemiology
• incidence 1/75 (Canada) 1/50 (US)
• risk factors: numerous moles, fair skin, red hair, positive personal/family history, large congenital nevi, familial dysplastic nevus syndrome, multiple dysplastic nevi
• most common sites: back (M), calves (F)
• worse prognosis if: male, on scalp, hands, feet, late lesion, no pre-existing nevus present

Differential Diagnosis
• benign: nevi, solar lentigo, seborrheic keratosis
• malignant: pigmented BCC

Management
• excisional biopsy preferable, otherwise incisional biopsy
• remove full depth of dermis and extend beyond edges of lesion only after histologic diagnosis
• beware of lesions that regress – tumour is usually deeper than anticipated
• high dose IFN for stage II (regional), chemotherapy (cis-platinum, BCG) and high dose IFN for stage III (distant) disease
• never chemotherapeutic, gene therapies and vaccines starting to be used in metastatic melanoma
• radiotherapy may be used as adjunctive treatment

a = no ulceration; b = ulceration

Other Cutaneous Cancers

CUTANEOUS T-CELL LYMPHOMA

Clinical Presentation
• Mycosis fungoides (limited superficial type)
  ▪ characterized by: erythematos patches/plaques/nodules/tumours, which may be pruritic and poikilodermic (atrophy, telangiectasia, hyperpigmentation)
  ▪ common sites include: trunk, buttocks, proximal limbs
  ▪ mildly symptomatic, usually excellent prognosis for early disease

• Sézary syndrome (widespread systemic type)
  ▪ rare variant characterized by: erythroderma, lymphadenopathy, WBC >20 x 10^9/L with Sézary cells
  ▪ associated with intense pruritus, alopecia, palmoplantar hyperkeratosis, and systemic symptoms (fatigue, fever)
  ▪ often fatal

Pathophysiology
• clonal proliferation of skin-homing CD4 T cells

Epidemiology
• >50 yr old, M:F 2:1
Differential Diagnosis
- tinea corporis, nummular dermatitis, psoriasis, discoid lupus erythematosus, Bowen’s disease

Investigations
- skin biopsy (histology, "lymphocyte antigen cell" markers, TcR gene arrangement)
- blood smear looking for Sézary cells or flow cytometry (e.g. CD4:CD8 >10 is Sézary)
- imaging (for systemic involvement)

Management
- Mycosis fungoides
  - treatment is dependent on stage of disease
  - topical steroids and/or PUVA, narrow band (311-313 nm), UVB (NBUVB)
- Sézary syndrome
  - oral retinoids and IFN
  - extra-corporeal photophoresis
  - may need radiotherapy for total skin electron beam radiation
  - may maintain on UV therapy
  - other chemotherapy agents

Alopecia (Hair Loss)

Hair Growth
- hair grows in a cyclic pattern that is defined in 3 stages
  1. growth stage = anagen phase
  2. transitional stage = catagen stage
  3. resting stage = telogen phase
- total duration of the growth stage reflects the type and location of hair: eyebrow, eyelash, and axillary hairs have a short growth stage in relation to the resting stage
- growth of the hair follicles is also based on the hormonal response to testosterone and DHT; this response is genetically controlled

Non-Scarring (Non-Cicatricial) Alopecia

ANDROGENETIC ALOPECIA

Clinical Presentation
- male-pattern or female-pattern alopecia
  - males: fronto-temporal areas progressing to vertex, entire scalp may be bald
  - females: widening of central part, “Christmas tree” pattern

Pathophysiology
- action of testosterone on hair follicles

Epidemiology
- males: early 20s-30s
- females: 40s-50s

Management
- minoxidil (Rogaine®) solution or foam to reduce rate of loss/partial restoration
- spironolactone in women (anti-androgenic effects), cyproterone acetate (Diane-35°)
- finasteride (Propecia®) (5-α-reductase inhibitor) 1 mg/d in men
- hair transplant

PHYSICAL
- trichotillomania: impulse-control disorder characterized by compulsive hair pulling with irregular patches of hair loss, and with remaining hairs broken at varying lengths
- traumatic (e.g. tight “corn-row” braiding of hair, wearing tight pony tails, tight tying of turbans)

TELOGEN EFFLUVIUM

Clinical Presentation
- uniform decrease in hair density secondary to hairs leaving the growth (anagen) stage and entering the resting (telogen) stage of the cycle
Pathophysiology
- precipitated by: malnutrition, Fe deficiency, thyroid dysfunction, post-partum/miscarriage, scalp diseases (seborrhoeic dermatitis, allergic contact dermatitis), medications (e.g. OCP), physical/mental stress
- hair loss typically occurs 2-4 mo after exposure to precipitant
- regrowth occurs within a few months but may not be complete

ANAGEN EFFLUVIUM

Clinical Presentation
- hair loss due to insult to hair follicle impairing its mitotic activity (growth stage)

Pathophysiology
- precipitated by chemotherapeutic agents (most common), other meds (bismuth, levodopa, colchicine, cyclosporine), exposure to chemicals (thallium, boron, arsenic)
- dose-dependent effect
- hair loss 7-14 d after single pulse of chemotherapy; most clinically apparent after 1-2 mo
- reversible effect; follicles resume normal mitotic activity few weeks after agent stopped

ALOPECIA AREATA

Clinical Presentation
- autoimmune disorder characterized by patches of complete hair loss often localized to scalp but can affect eyebrows, beard, eyelashes, etc.
- may be associated with dystrophic nail changes – fine stippling, pitting
- “exclamation mark” pattern (hairs fractured and have tapered shafts, i.e. looks like “!”)
- may be associated with pernicious anemia, vitiligo, thyroid disease, Addison’s disease
- spontaneous regrowth may occur within months of first attack (worse prognosis if young at age of onset and extensive loss)
- frequent recurrence often precipitated by emotional distress

Management
- generally unsatisfactory
- intralesional triamcinolone acetonide (corticosteroids) can be used for isolated patches
- UV or PUVA therapy
- immunomodulatory (diphencyprone)

Scarring (Cicatricial) Alopecia

Clinical Presentation
- irreversible loss of hair follicles with fibrosis

Etiology
- physical: radiation, burns
- infections: fungal, bacterial, TB, leprosy, viral (HZV)
- inflammatory
  - lichen planus (lichen planopilaris)
  - DLE (note that SLE can cause an alopecia unrelated to discoid lupus lesions which are non-scarring)
  - morphoea: “coup de sabre” with involvement of centre of scalp
- central centrifugal cicatricial alopecia: seen in up to 40% of black women, starting at central scalp; one of most commonly diagnosed scarring alopecias, may be associated with hair care practices in this population

Investigations
- biopsy from active border

Management
- infections: treat underlying infection
- inflammatory: topical/intralesional steroids, anti-inflammatory antibiotics, antimalarials

DDx of Scarring (cicatricial) Alopecia

Developmental/Hereditary Disorders
- Aplasia cutis congenita
- Epidermal nevi
- Romberg’s syndrome
- Generalized follicular hamartoma

Primary causes
- Group 1: Lymphocytic
  - Discoid lupus erythematosus
  - Lichen planopilaris
  - Central centrifugal cicatricial alopecia
  - Classic Pseudopelade
- Group 2: Neutrophilic
  - Folliculitis decalvans
  - Dissecting scalp cellulitis
- Group 3: Mixed
  - Acne keloidalis nuchae

Secondary causes
- Infectious agents
  - Bacterial (e.g. post-cellulitis)
  - Fungal (e.g. tinea capitis)
  - Neoplasms (e.g. BCC, SCC, lymphomas, and metastatic tumours)
- Physical agents
  - Mechanical trauma
  - Burns
  - Radiotherapy
  - Caustic chemicals
### Nails and Disorders of the Nail Apparatus

### Pediatric Exanthems

**Definitions**
- Exanthem: an eruption on the skin occurring as a symptom of a systemic disease typically with a fever.
- Exanthem: an eruption on a mucous membrane occurring in the context of an exanthem.

</tbody>
</table>

### Miscellaneous Lesions

#### Angioedema and Urticaria

**Angioedema**
- Deeper swelling of the skin involving subcutaneous tissues; often involves the eyes, lips, and tongue
- May or may not accompany urticaria
- Hereditary or acquired forms
- Hereditary angioedema (does not occur with urticaria)
  - Onset in childhood; 80% have positive family history
  - Recurrent attacks; 25% die from laryngeal edema
  - Triggers: minor trauma, emotional upset, temperature changes
- Treatment
  - Prophylaxis with danazol or stanozolol for hereditary angioedema
  - Epinephrine pen to temporize until patient reaches hospital in acute attack

**Urticaria**
- Also known as “hives”; see Table 26 for classification
- Transient, red, pruritic well-demarcated wheals
- Each individual lesion lasts less than 24 h
- Second most common type of drug reaction
- Results from release of histamine from mast cells in dermis
- Can also result after physical contact with allergen
Table 26. Classification of Urticaria

<table>
<thead>
<tr>
<th>Type</th>

Erythema Nodosum

Clinical Presentation
- acute or chronic inflammation of subcutaneous fat (panniculitis)
- round, red, tender, poorly demarcated nodules
- sites: asymmetrical on extensor lower legs, knees, arms, (typically shins)
- associated with arthralgia, fever, malaise

Etiology
- 40% are idiopathic
- drugs: sulfonamides, oral contraceptives (also pregnancy), analgesics, trans retinoic acid
- infections: GAS, TB, histoplasmosis, Yersinia
- inflammation: sarcoidosis, Crohn's > UC
- malignancy: acute leukemia, Hodgkin's lymphoma

Epidemiology
- 15-30 yr old, F:M = 3:1
- lesions last for days and spontaneously resolve in 6 wk

Investigations
- chest x-ray (to rule out chest infection and sarcoidosis)
- throat culture, antistreptolysin (ASO) titre, purified protein derivative (PPD) skin test

Management
- symptomatic: bed rest, compressive bandages, wet dressings
- NSAIDs, intralesional steroids
- treat underlying cause

DDx of Erythema Nodosum

NODOSUMM
No cause (idiopathic) in 40%
Drugs (sulfonamides, OCP, etc.)
Other infections (GAS+)
Sarcoidosis
Ulcerative colitis and Crohn's
Malignancy (leukemia, Hodgkin's lymphoma)
Many Infections

DDx for Urticaria

DAM HIVES
Drugs and foods

Malignancy
Hereditary
Infection
Vasculitis
Emotions
Stings

Approach to Urticaria
- Thorough Hx and P/E
- Acute: if individual lesions last <24 h, but attacks last <6 wk; no immediate investigations needed; consider referral for allergy testing
- Chronic: if individual lesions last <24 h but attacks last >6 wk; further investigations required: CBC and differential, urinalysis, ESR, TSH, LFTs to help identify underlying cause
- Vasculitic: if individual lesions last >24 h; biopsy of lesion and referral to dermatology

Mastocytosis (Urticaria Pigmentosa)
Rare disease due to excessive infiltration of the skin by mast cells. It manifests as many reddish-brown elevated plaques and macules. Friction to a lesion produces a wheal surrounded by intense erythema (Barter’s sign), due to mast cell degranulation. This occurs within minutes.
**Pruritus**

**Clinical Presentation**
- a sensation provoking a desire to scratch
- pruritus can present with or without skin lesions
- lesions may arise from the underlying disease, or from excoriation causing crusts, lichenified plaques, or wheals

**Etiology**
- dermatologic – generalized
  - atopic and contact dermatitis, lichen planus, urticaria, insect bites, dermatitis herpetiformis
  - infection: varicella, candidiasis
  - lichen simplex chronicus
  - prurigo nodularis
- systemic disease – usually generalized
  - hepatic: obstructive biliary disease, cholestatic liver disease of pregnancy
  - renal: chronic renal failure, uremia secondary to hemodialysis
  - hematologic: Hodgkin’s lymphoma, multiple myeloma, leukemia, polycythemia vera, hemochromatosis, Fe deficiency anemia, cutaneous T-cell lymphoma
  - neoplastic: lung, breast, gastric (internal solid tumours), non-Hodgkin’s lymphoma
  - endocrine: carcinoid, DM, hypothyroid/thyrotoxicosis
  - infectious: HIV, trichinosis, echinococcosis, hepatitis C
  - psychiatric: depression, psychosis
  - neurologic: post-herpetic neuralgia, multiple sclerosis

**Investigations**
- detailed history
- complete physical, including rectal and pelvic examination
- bloodwork: CBC, ESR, Cr/BUN, LFT, TSH, fasting blood sugar, stool culture and serology for parasites

**Management**
- treat underlying cause
- cool water compresses to relieve pruritus
- bath oil and emollient ointment (especially if xerosis is present)
- topical corticosteroid and antipruritics (e.g. menthol, camphor, phenol, mirtazapine, capsaicin)
- systemic antihistamines: H1 blockers are most effective, most useful for urticaria
- phototherapy with UVB or PUV A
- doxepin, amitryptyline
- immunosuppressive agents if severe: steroids and steroid sparing

**Wounds and Ulcers**
- see Plastic Surgery: PS8, PS15

**Common Medications**

**Sunscreens and Preventative Therapy**

**Sunburn**
- erythema 2-6 h post UV exposure often associated with edema, pain and blistering with subsequent desquamation of the dermis, and subsequent hyperpigmentation
- chronic UVA, UVB exposure leads to photoaging, immunosuppression, photocarcinogenesis
- prevention: avoid peak UVR (10 am to 4 pm), wear appropriate clothing, wide-brimmed hat, sunglasses, and broad-spectrum sunscreen
- clothing with UV protection expressed as UV protection factor (UPF) is analogous to SPF of sunscreen
Sunscreens
- under ideal conditions an SPF of 10 means that a person who normally burns in 20 min will burn in 200 min following the application of the sunscreen
- topical chemical: absorbs UV light
  - requires application at least 15-60 min prior to exposure, should be reapplied every 2 h
    (more often if sweating, swimming)
  - UVB absorbers: PABA, salicylates, cinnamates, benzylidine camphor derivatives
  - UVA absorbers: benzophenones, anthranilates, dibenzoylmethanes, benzylidine camphor derivatives
- topical physical: reflects and scatters UV light
  - titanium dioxide, zinc oxide, kaolin, talc, ferric chloride and melanin
- all are effective against the UVA and UVB spectrum
- less risk of sensitization than chemical sunscreens and waterproof, but may cause folliculitis or miliaria
- some sunscreen ingredients may cause contact or photocontact allergic reactions, but are uncommon

Management
- sunburn: if significant blistering present, consider treatment in hospital; otherwise, symptomatic treatment (cool wet compresses, oral anti-inflammatory, topical corticosteroids)
- antioxidants, both oral and topical are being studied for their abilities to protect the skin; topical agents are limited by their ability to penetrate the skin

### Topical Steroids

#### Table 27. Potency Ranking of Topical Steroids

<table>
<thead>
<tr>
<th>Relative Potency</th>
<th>Relative Strength</th>
<th>Generic Names</th>
<th>Trade Names</th>

</tbody>
</table>

Calculation of strength of steroid compared to hydrocortisone on forearm: relative strength of steroid x relative percutaneous absorption

#### Side Effects of Topical Steroids

- Local: Atrophy
- Percutaneous dermatitis
- Steroid acne
- Rosacea
- Contact dermatitis
- Tachyphylaxis (tolerance)
- Systemic: Suppression of HPA axis

#### Dermatologic Therapies

#### Table 28. Common Topical Therapies

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calcipotriol (Dovonex®)</td>
<td>0.005% cream, ointment, scalp solution, apply bid For maintenance therapy apply OD</td>
<td>Psoriasis</td>
<td>Burning, itching, skin irritation, worsening of psoriasis Avoid face, mucous membranes, eyes; wash hands after application Maximum weekly dosage of cream by age: 2.5 yr – 25 g/wk 6-10 yr – 50 g/wk 11-14 yr – 75 g/wk &gt;14 yr – 100 g/wk Inactivated by light (do not apply before phototherapy)</td>
</tr>
<tr>
<td>Imiquimod (Aldara®)</td>
<td>5% cream applied 3x/wk Apply at bedtime, leave on 6-10 h, then wash off with mild soap and water Max duration 16 wk</td>
<td>Genital warts Cutaneous warts Actinic keratosis Superficial BCC</td>
<td>Avoid natural/artificial sun exposure Local skin and application site reactions Works best for warts on mucosal surfaces May induce inflammation and erosion</td>
</tr>
</tbody>
</table>

#### Vehicles

- Ointment (water in oil): hydrate, greasy
- Cream (oil in water): hydrate, variable
- Lotion (powder in water): drying, cosmesis
- Solutions (water, alcohol, propylene glycol)
- Gel (solution that melts on contact with skin, alcohol): drying
**Table 28. Common Topical Therapies (continued)**

<table>

<th>Drug Name</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Permethrin</strong>&lt;br&gt;(Kwellada® P Lotion and Nix® Dermal Cream)</td>
<td>5% cream, applied once overnight to all skin areas from neck down, repeated one week later</td>
<td>Scabies (Kwellada-P Lotion, Nix® Dermal Cream) Pediculosis (Kwellada-P Crème Rinse®, Nix Crème Rinse®)</td>
<td>Do not use in children &lt;2 yr old&lt;br&gt;Hypersensitivity to drug, or known sensitivity to chrysanthemums&lt;br&gt;Local reactions only (resolve rapidly); including burning, pruritus&lt;br&gt;Low toxicity, excellent results&lt;br&gt;Consider 2nd application after 7 d</td>
</tr>
<tr>
<td><strong>Pimecrolimus</strong>&lt;br&gt;(Elidel®)</td>
<td>1.0% cream bid&lt;br&gt;Use for as long as lesions persist and discontinue upon resolution of symptoms</td>
<td>AD (mild to moderate)</td>
<td>Burning&lt;br&gt;Lacks adverse effects of steroids&lt;br&gt;May be used on all skin surfaces including head, neck, and intertriginous areas&lt;br&gt;Expensive</td>
</tr>
<tr>
<td><strong>Tacrolimus topical</strong>&lt;br&gt;(Protopic®)</td>
<td>0.03% (children) or 0.1% (adults) ointment bid&lt;br&gt;Continue for duration of disease PLUS x 1 wk after clearing</td>
<td>AD (mild to moderate)</td>
<td>Burning&lt;br&gt;Lacks adverse effects of steroids&lt;br&gt;May be used on all skin surfaces including head, neck, and intertriginous areas&lt;br&gt;Expensive</td>
</tr>
</tbody>
</table>

**Table 29. Common Oral Therapies**

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Acitretin</strong>&lt;br&gt;(Soriatane®)</td>
<td>25-50 mg PO OD; maximum 75 mg/d</td>
<td>Severe psoriasis&lt;br&gt;Other disorders of hyperkeratinization (ichthyosis, Darier’s disease)</td>
<td>Monitoring strategies:&lt;br&gt;Monitor lipids, LFTs at baseline and q1-2wk until stable&lt;br&gt;Contraindications:&lt;br&gt;Women of childbearing potential unless strict contraceptive requirements are met&lt;br&gt;Drug interactions:&lt;br&gt;Other systemic retinoids, methotrexate, tetracyclines, certain contraceptives&lt;br&gt;May be combined with PUVA phototherapy (known as re-PUVA)</td>
</tr>
<tr>
<td><strong>Antivirals</strong>&lt;br&gt;Famcyclovir (Famvir®)</td>
<td>250 mg PO tid x 7-10 d&lt;br&gt;(for 1st episode of genital herpes)&lt;br&gt;125 mg PO bid x 5d&lt;br&gt;(for recurrent genital herpes)</td>
<td>Chickenpox&lt;br&gt;Herpes zoster&lt;br&gt;Genital herpes&lt;br&gt;Acute and prophylactic to reduce transmission in infected patients&lt;br&gt;Herpes labialis</td>
<td>Side effects:&lt;br&gt;Headache, nausea, diarrhea, abdominal pain&lt;br&gt;Reduce dose if impaired renal function</td>
</tr>
<tr>
<td>Valacyclovir (Valtrex®)</td>
<td>1000 mg PO bid x 7-10 d&lt;br&gt;(for 1st episode of genital herpes)&lt;br&gt;500 mg PO bid x 5 d&lt;br&gt;(for recurrent genital herpes)</td>
<td></td>
<td>Side effects:&lt;br&gt;Dizziness, depression, abdominal pain&lt;br&gt;Reduce dose if impaired renal function&lt;br&gt;Drug interactions:&lt;br&gt;cimetidine</td>
</tr>
<tr>
<td><strong>Cyclosporin</strong>&lt;br&gt;(Neoral®)</td>
<td>2.5-4 mg/kg/d PO div bid&lt;br&gt;Max 4 mg/kg/d&lt;br&gt;After 4 wk may increase by 0.5 mg/kg/d q2wks&lt;br&gt;Concomitant dose of magnesium may protect the kidneys</td>
<td>Psoriasis&lt;br&gt;May also be effective in: Lichen planus&lt;br&gt;EM&lt;br&gt;Recalcitrant urticaria&lt;br&gt;Recalcitrant AD</td>
<td>Monitoring strategies:&lt;br&gt;Blood pressure, renal function&lt;br&gt;Contraindications:&lt;br&gt;Abnormal renal function, uncontrolled hypertension, malignancy (except non-melanoma skin cancer), uncontrolled infection, immunodeficiency (excluding autoimmune disease), hypersensitivity to drug&lt;br&gt;Long term effects preclude use of cyclosporin for &gt;2 yr; discontinue earlier if possible&lt;br&gt;May consider rotating therapy with other drugs to minimize adverse effects of each drug</td>
</tr>
<tr>
<td><strong>Dapsone</strong></td>
<td>50-100-150 mg PO OD tapering to 25-50 mg PO OD to as low as 50 mg 2x/wk</td>
<td>Dermatitis herpetiformis, neutrophilic dermatoses</td>
<td>Monitoring strategies:&lt;br&gt;Obtain GSPD levels before initiating; in the initial two wk obtain methemoglobin levels and follow the blood counts carefully for the first few months&lt;br&gt;Side effects:&lt;br&gt;Neuropathy&lt;br&gt;Hemolysis (Vitamin C and E supplementation can help prevent this)&lt;br&gt;Drug interactions:&lt;br&gt;Substrate of CYP2C8/9 (minor), 2C19 (minor), 2E1 (minor), 3A4 (major)&lt;br&gt;Often a dramatic response within hours</td>
</tr>
</tbody>
</table>

<tr>
<td></td>
<td></td>
<td></td>
<td>Do not use at the same time as tetracycline or minocycline – both may cause pseudotumour cerebri</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Drug may be discontinued at 16-20 wk when nodule count has dropped by &gt;70%. A second course may be initiated after 2 mo pm</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Refractory cases may require &gt;3 courses</td>
</tr>
<tr>
<td><strong>Itraconazole</strong> (Sporanox®)</td>
<td>100-400 mg PO OD, depending on infection treated</td>
<td>Onychomycosis Tinea corporis, cruris, pedis, versicolor, capsitis</td>
<td>Contraindications: CHF</td>
</tr>
<tr>
<td></td>
<td>Tinea corporis/cruris: 200 mg PO OD x 7 d</td>
<td></td>
<td>Side effects: Serious hepatotoxicity</td>
</tr>
<tr>
<td></td>
<td>Tinea pedis: 200 mg PO bid x 7 d</td>
<td></td>
<td>Drug Interactions: Inhibits CYP 3A4. Increases concentration of some drugs metabolized by this enzyme (i.e. statins, diabetic drugs)</td>
</tr>
<tr>
<td></td>
<td>Tinea versicolor: 200 mg PO OD x 7 d</td>
<td></td>
<td>Give capsules with food, capsules must be swallowed whole</td>
</tr>
<tr>
<td></td>
<td>Toenails with or without fingernail involvement: 200 mg PO bid x 7 d once per month, repeated 3x</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Fingernail involvement only: 200 mg bid PO x 7 d once per month, repeated 2x</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Ivermectin</strong> (Mectizan®, Stromectol®)</td>
<td>200-250 µg/kg PO qweekly x 2</td>
<td>Onchocerciasis (USA only) Not licensed for use in Canada Also effective for: Scabies</td>
<td>No significant serious side effects</td>
</tr>
<tr>
<td></td>
<td>Take once as directed; repeat one wk later</td>
<td></td>
<td>Efficacious</td>
</tr>
<tr>
<td><strong>Methotrexate</strong> (Trexall®)</td>
<td>10-25 mg qwk, PO, IM, or IV Max: 30 mg/ivk</td>
<td>Psoriasis AD Lymphomatoid papulosis May also be effective in: Cutaneous sarcoidosis</td>
<td>Monitoring strategies: Baseline renal, liver, and hematological studies</td>
</tr>
<tr>
<td></td>
<td>To minimize side effects, administer with folic acid supplementation: 1-5 mg OD</td>
<td></td>
<td>Contraindications: Pregnancy, lactation, alcohol abuse, liver dysfunction, immunodeficiency syndrome, blood dyscrasias, hypersensitivity to drug</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Restricted to severe, recalcitrant or disabling psoriasis not adequately responsive to other forms of therapy</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>May be combined with cyclosporine to allow lower doses of both drugs</td>
<td></td>
</tr>
<tr>
<td><strong>Minocycline</strong> (Minocin®)</td>
<td>50-100 mg PO bid Taper to 50 mg PO OD as acne lessens</td>
<td>Acne vulgaris Rosacea</td>
<td>Contraindications: Caution if impaired renal or liver function</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Drug interactions: Do not use with isotretinoin (Accutane®)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Side effects: Extensive; affects multiple organ systems including CNS, teeth, eyes, bones, renal, and skin (photosensitivity, and blue pigmentation) Drug-induced lupus (check p-ANCA) Alternative to tetracycline</td>
</tr>
<tr>
<td><strong>Terbinafine</strong> (Lamisil®)</td>
<td>250 mg PO OD x 2 wk Finger nails x 6 wk Toenails x 12 wk Confirm diagnosis prior to treatment</td>
<td>Onychomycosis Tinea corporis, cruris, pedis, capsitis</td>
<td>Contraindications: Pregnancy, chronic or active liver disease</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Drug interactions: Potent inhibitor of CYP 2D6; use with caution when also taking β-blockers, certain anti-arrhythmic agents, MAOI type B, and/or antipsychotics</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Drug concentrates rapidly in skin, hair and nails at levels associated with fungicidal activity</td>
</tr>
<tr>
<td><strong>Tetracycline</strong></td>
<td>250-500 mg PO bid to tid Taken 1 h before or 2 h after a meal</td>
<td>Acne vulgaris Rosacea Bullous pemphigoid</td>
<td>Contraindications: Severe renal or hepatic dysfunction</td>
</tr>

## Initial Patient Assessment/Management

### 1. Rapid Primary Survey (RPS)

- Airway maintenance with cervical spine (C-spine) control
- Breathing and ventilation
- Circulation (pulses, hemorrhage control)
- Disability (neurological status)
- Exposure (complete) and Environment (temperature control)
- Continually reassessed during secondary survey

**IMPORTANT:** always watch for signs of shock while doing primary survey (see Table 1)

#### A. AIRWAY

- First priority is to secure airway
- Assume a cervical injury in every trauma patient and immobilize with collar
- Assess ability to breathe and speak
- Can change rapidly, therefore reassess frequently

**Airway Management**

- Permit adequate oxygenation and ventilation

1. **Basic Airway Management (Temporizing Measures)**
   - Protect the C-spine
   - Head-tilt (if C-spine injury not suspected) or jaw thrust to open the airway
   - Sweep and suction to clear mouth of foreign material

2. **Temporizing Measures**
   - Nasopharyngeal airway (if gag reflex present, i.e. conscious)
   - Oropharyngeal airway (if gag reflex absent, i.e. unconscious)
   - "Rescue" airway devices [e.g. laryngeal mask airway (LMA); Combitube™]
   - Transtracheal jet ventilation through cricothyroid membrane (last resort)

3. **Definitive Airway Management**
   - ETT intubation with in-line stabilization of C-spine (Figure 1)
     - Orotracheal ± RSI preferred
     - Nasotracheal – may be better tolerated in conscious patient
       - Relatively contraindicated with basal skull fracture
     - Does not provide 100% protection against aspiration
   - Surgical airway (if unable to intubate using oral/nasal route and unable to ventilate)
     - Cricothyroidotomy

**Contraindications to Intubation**

- Supraglottic/glottic pathology that would preclude successful intubation
B. BREATHING

- Look
  - mental status (anxiety, agitation, decreased LOC), colour, chest movement (bilateral vs. asymmetrical), respiratory rate/effort, nasal flaring
- Listen
  - auscultate for signs of obstruction (e.g. stridor), breath sounds, symmetry of air entry, air escaping
- Feel
  - tracheal shift, chest wall for crepitus, flail segments, sucking chest wounds, subcutaneous emphysema

Breathing Assessment
- objective measures of respiratory function: rate, oximetry, arterial blood gas (ABG), A-a gradient

Management of Breathing
- nasal prongs → simple face mask → non-rebreather mask → CPAP/BiPAP (in order of increasing FiO2)
- Venturi mask: used to precisely control O2 delivery
- Bag-Valve mask and CPAP to supplement inadequate ventilation

C. CIRCULATION

Definition of Shock
- inadequate organ and tissue perfusion with oxygenated blood (brain, kidney, extremities) (see Table 2)

Table 1. Major Types of Shock

<td></td>
<td>Constrictive periarteritis</td>
</tr>
</tbody>
</table>

Clinical Evaluation
- early: tachypnea, tachycardia, narrow pulse pressure, reduced capillary refill, cool extremities and reduced central venous pressure (CVP)
- late: hypotension and altered mental status, reduced urine output

</table>

Shock in a trauma patient is hemorrhagic until proven otherwise.

Signs of Fluid Depletion
- Increased heart rate
- Postural changes in vital signs
- Decreased urine output
- Hypotensive
- Decreased skin turgor
- Sunken eyes
- Decreased capillary refill

Causes of Shock

SHOCKED
- Sepsis (spinal/neurogenic, Hemorrhagic
- Obstructive (e.g. tension pneumonia, cardiac tamponade, pulmonary embolism)
- Cardiogenic (e.g. blunt myocardial injury, dysrhythmia, MI)
- Anaphylactic
- Endocrine (e.g. Addison’s, myxedema, coma)
- Drugs

</tbody>
</table>
Management of Hemorrhagic Shock

- ABCs
  - diagnose and manage underlying cause
  - if bleeding externally, apply direct pressure and elevate extremities if possible
  - do not remove impaled objects as they tamponade hemorrhage
  - tourniquet as a last resort
- resuscitation
  - infuse 1-2 L of crystalloid with large bore IVs (warmed if possible)
  - if inadequate response, consider acute internal bleeding (e.g., chest, abdomen, pelvis, femurs), will likely require surgical intervention
  - if severely hypotensive on arrival or if shock persists, consider pRBC transfusion
  - transfuse crossmatched (ideally) or type-specific blood if available
  - if unavailable, transfuse O-negative in children/women of child bearing age or O-positive in all others
- with significant blood loss, early transfusion of platelets and FFP may improve outcomes

D. DISABILITY
- assess level of consciousness by AVPU method or GCS (Table 3)

Glasgow Coma Scale (GCS)
- for use in trauma patients with decreased LOC; good indicator of severity of injury and neurosurgical prognosis
- most useful if repeated and used for monitoring of trend
- change in GCS with time is more relevant than the absolute number
- less meaningful for metabolic coma
- patient with deteriorating GCS needs immediate attention
- prognosis based on best post-resuscitation GCS
- reported as a 3 part score: Eyes + Verbal + Motor = Total (see Table 3)
- if patient intubated, GCS score reported out of 10 + T (T= tubed, i.e. no verbal component)

Table 3. Glasgow Coma Scale

<table>
<thead>
<tr>

<td>Decerebrate (extension)</td>
</tr>
</tbody>
</table>

13-15 = mild injury, 9-12 = moderate injury, ≤8 = severe injury
See Table 30 for modified GCS for infants and children

E. EXPOSURE/ENVIRONMENT
- undress patient completely and assess entire body for injury; logroll to examine back
- digital rectal exam
- keep patient warm with a blanket ± radiant heaters; avoid hypothermia
- warm IV fluids/blood
- keep providers safe (contamination, combative patient)

2. Resuscitation

- done concurrently with primary survey
- attend to ABCs (see Table 4)
- manage life-threatening problems as they are identified
- vital signs q5-15 min
- ECG, BP and O₂ monitors
- Foley catheter and NG tube if indicated
- tests and investigations: CBC, electrolytes, BUN, Cr, glucose, amylase, INR/PTT, β-hCG, toxicology screen, cross and type

Fluid Resuscitation
- Give bolus until HR decreases, urine output increases, and patient stabilizes
- Maintenance: 4:2:1 rule
- 0-10 kg: 4 cc/kg/h
- 10-20 kg: 2 cc/kg/h
- Remaining weight: 1 cc/kg/h
- Replace ongoing losses and deficits (assume 10% of body weight)

3:1 Rule
Since only 30% of infused isotonic crystalloids remains in intravascular space, you must give 3x estimated blood loss.

Vasopressin versus Norepinephrine Infusion in Patients with Septic Shock
NEJM 2008;358:877-87
Study: Multicentre, randomized, double-blind trial
Patients: 778 patients with septic shock
Intervention: Low-dose vasopressin (0.01 to 0.03 U per minute) or norepinephrine (5 to 15 ug per minute) in addition to open-label vasopressors and a minimum of 5 ug of norepinephrine.
Outcome: Mortality rate 28 d after start of infusions.
Results: No significant difference between the vasopressin and the norepinephrine groups at 28 d or 90 d. However, in patients with less severe septic shock, mortality rate was lower in the vasopressin group.

Contraindications to Foley insertion
- Blood at urethral meatus
- Scrotal hematoma
- High-riding prostate on DRE
Table 4. 2010 AHA CPR Guidelines

</tr>
</tbody>
</table>

3. Secondary Survey

- done after rapid primary survey problems have been addressed
- identifies major injuries or areas of concern
- full physical exam and x-rays (C-spine, chest, pelvis – required in blunt trauma, consider T-spine and L-spine)

**HISTORY**

- “SAMPLE”: Signs and symptoms, Allergies, Medications, Past medical history, Last meal, Events related to injury

**PHYSICAL EXAMINATION**

**Head and Neck**

- pupils
  - assess equality, size, symmetry, reactivity to light
  - inequality/sugglish suggests local eye problem or lateralizing CNS lesion
  - relative afferent pupillary defect (swinging light test) – optic nerve damage
  - extraocular movements and nystagmus
  - fundoscopy (papilledema, hemorrhages)
  - reactive pupils + decreased LOC \(\rightarrow\) metabolic or structural cause
  - non-reactive pupils + decreased LOC \(\rightarrow\) structural cause (especially if asymmetric)
  - palpation of facial bones, scalp

**Chest**

- inspect for midline trachea, flail segment: \(\geq 2\) rib fractures in \(\geq 2\) places; if present look for associated hemothorax, pneumothorax, and contusions
- auscultate lung fields
- palpate for subcutaneous emphysema
- CXR

**Abdomen**

- assess for peritonitis, abdominal distention, and evidence of intra-abdominal bleeding
- FAST or CT (if stable)
- rectal exam for GI bleed, high riding prostate and anal tone (best to do during the log roll)
- bimanual exam in females as appropriate

**Musculoskeletal (MSK)**

- examine all extremities for swelling, deformity, contusion, tenderness, ROM
- check for pulses and sensation in all injured limbs
- log roll and palpate thoracic and lumbar spines
- palpate iliac crests and pubic symphysis, pelvic stability (lateral, AP, vertical)
- pelvic x-ray

---

**NG Tube Contraindications**

- Significant mid-face trauma
- Basal skull fracture

See Anesthesia, A28 for 2012 ACLS Guidelines.
Neurological
- GCS
- full cranial nerve exam
- alterations of rate and rhythm of breathing are signs of structural or metabolic abnormalities
  ▪ progressive deterioration of breathing pattern implies a failing CNS
- assess spinal cord integrity
  ▪ conscious patient: assess distal sensation and motor
  ▪ unconscious patient: response to painful or noxious stimulus applied to extremities

Ethical Considerations

Consent to Treatment: Adults
- see Ethical, Legal and Organizational Aspects of Medicine, ELOAM5
- Emergency Rule: consent is not needed when a patient is at imminent risk from a serious injury
  AND obtaining consent is either: a) not possible OR b) would increase risk to the patient
  ▪ assumes that most people would want to be saved in an emergency
- any capable and informed patient can refuse treatment or part of treatment, even if it is life-saving
- exceptions to the Emergency Rule: treatment cannot be initiated if
  ▪ a competent patient has previously refused the same or similar treatment and there is no evidence to suggest the patient's wishes have changed
  ▪ an advanced directive is available – e.g. do not resuscitate (DNR) order
  ▪ NOTE: refusal of help in a suicide situation is NOT an exception; care must be given
- if in doubt, initiate treatment
  ▪ care can be withdrawn if necessary at a later time or if wishes are clarified by family

Consent to Treatment: Children
- treat immediately if patient is at imminent risk
- parents/guardians have the right to make treatment decisions
- if parents refuse treatment that is life-saving or will potentially alter the child's quality of life, Children's Aid Society (CAS) must be contacted – consent of CAS is needed to treat

Other Issues of Consent
- need consent for HIV testing, as well as for administration of blood products
- however, if delay in substitute consent for blood transfusions puts patient at risk, transfusions can be given

Duty to Report
- law may vary depending on province and/or state
- examples: gunshot wounds, potential drunken drivers, suspected child abuse, various communicable diseases, medical unsuitability to drive, risk of substantial harm to others

Traumatology

- epidemiology
  ▪ leading cause of death in patients <45 yr
  ▪ 4th highest cause of death in North America
  ▪ causes more deaths in children/adolescents than all diseases combined
- trimodal distribution of death
  ▪ minutes: lethal injuries, death usually at the scene
  ▪ early: death within 4-6 h – “golden hour” (decreased mortality with trauma care)
  ▪ days-weeks: death from multiple organ dysfunction, sepsis, etc.
- injuries fall into two categories
  ▪ blunt (most common): motor vehicle collision (MVC), pedestrian-automobile impact, motorcycle collision, fall, assault, sports
  ▪ penetrating (increasing in incidence): gunshot wound, stabbing, impalement

Jehovah’s Witnesses
- Capable adults have the right to refuse medical treatment
- May refuse whole blood, pRBCs, platelets and plasma even if life-saving
- Should be questioned directly about the use of albumin, immunoglobulins, hemophilic preparations
- Do not allow autologous transfusion unless there is uninterrupted extracorporeal circulation
- Usually ask for the highest possible quality of care without the use of the above interventions (e.g. crystalloids for volume expansion, attempts at bloodless surgery)
- Patient will generally sign hospital forms releasing medical staff from liability
- Most legal cases involve children of Jehovah’s Witnesses; if life-saving treatment is refused contact CAS
Considerations for Traumatic Injury

• important to know the mechanism of injury in order to anticipate traumatic injuries
• always look for an underlying cause (alcohol, medications, illicit substances, seizure, suicide attempt, medical problem)
• always inquire about head injury, loss of consciousness, amnesia, vomiting, headache and seizure activity

Table 5. Mechanisms and Considerations of Traumatic Injuries

<table>
<thead>
<tr>
<th>Mechanism of Injury</th>
<th>Special Considerations</th>
<th>Associated Injuries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Motor Vehicle Collision</td>
<td>Vehicle(s) involved: weight, size, speed, damage, Location of patient in vehicle</td>
<td>Head-on collision: head/facial, thoracic (aortic), lower extremity, lateral/T-bone</td>
</tr>
<tr>
<td></td>
<td>Use and type of seatbelt, Ejection of patient from vehicle, Entrapment of patient under vehicle</td>
<td>collision: head, cervical spine, thoracic, abdominal, pelvic and lower extremity.</td>
</tr>
<tr>
<td></td>
<td>Airbag deployment, Helmet use in motorcycle collision</td>
<td>Rear-end collision: hyper-extension of cervical spine (whiplash injury) Rollover</td>
</tr>
<tr>
<td>Pedestrian-Automobile Impact</td>
<td>High morbidity and mortality, Vehicle speed is an important factor, Site of impact on car</td>
<td>Children at increased risk of being run over (multisystem injuries) Adults tend to be struck in lower legs (lower extremity injuries), impacted against car (truncal injuries) and thrown to ground (head injuries)</td>
</tr>
<tr>
<td>Falls</td>
<td>1 storey = 12 feet = 3.6 m, Distance of fall: 50% mortality at 4 stories and 95% mortality at 7 stories, Landing position (vertical vs. horizontal)</td>
<td>Vertical: lower extremity, pelvic and spine fractures, Head injuries Horizontal: facial, upper extremity and rib fractures, Abdominal, thoracic and head injuries</td>
</tr>
<tr>
<td>Gunshot Wounds (GSW)</td>
<td>Type of gun, Type of ammunition, Range of shot, Characterize route of entry, even or odd number of wounds and site of exit wound (if any) KE = 1/2 mv^2</td>
<td>Injuries dependent on location of GSW and underlying structures Hand gun: low/medium velocity, extent of injury may be limited to small area Hunting rifle: high velocity, widespread injury Shotgun: widespread tissue destruction at close range, massive tissue destruction, deposition of wadding into wound</td>
</tr>
<tr>
<td>Stab Wounds (SW)</td>
<td>Route/direction of entry, Length of blade, Type of penetration (stab, slash, impalement), If blade in-situ, DO NOT REMOVE – may be tamponading vessel (to be removed in OR)</td>
<td>Injuries dependent on location of SW and underlying structures</td>
</tr>
</tbody>
</table>

Head Trauma

• see Neurosurgery, NS30
• 60% of trauma admissions have head injuries
• 60% of MVC-related deaths are due to head injury

Specific Injuries

• fractures
  • Dx: non-contrast head CT and physical exam
  A. skull fractures
    • vault fractures
      • linear, non-depressed
        – most common
        – typically occur over temporal bone, in area of middle meningeal artery (commonest cause of epidural hematoma)
      • depressed
        – open (associated overlying scalp laceration and torn dura), skull fracture disrupting paranasal sinuses or middle ear) vs. closed
    • basal skull
      • typically occur through floor of anterior cranial fossa (longitudinal more common than transverse)
      • clinical diagnosis superior as poorly visualized on CT (Battle’s sign, raccoon eyes, CSF rhinorrhea/otorrhea, hemotympanum)
  B. facial fractures (see Plastic Surgery, PL28)
    • neuronal injury
    • beware of open fracture or sinus fractures (risk of infection)
    • unstable or displaced fractures (need semi-urgent plastics referral)
    • severe facial fractures may pose risk to airway from profuse bleeding

Cardiac box: sternal notch, nipples and xiphoid process; injuries inside this area should increase suspicion of cardiac injury.

Always completely expose and count the number of wounds.
• **scalp laceration**  
  ▪ can be a source of significant bleeding  
  ▪ achieve hemostasis, inspect and palpate for skull bone defects ± CT head (rule-out skull fracture)

• **neuronal injury**
  A. **diffuse**  
  ▪ mild traumatic brain injury = concussion  
  ▪ transient alteration in mental status that may involve loss of consciousness  
  ▪ hallmarks of concussion: confusion and amnesia, which may occur immediately after the trauma or minutes later  
  ▪ loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15 and post-traumatic amnesia must be less than 24 h
  ▪ diffuse axonal injury  
  ▪ mild: coma 6-24 h, possibly lasting deficit
  ▪ moderate: coma >24 h, little or no signs of brainstem dysfunction
  ▪ severe: coma >24 h, frequent signs of brainstem dysfunction
  B. **focal injuries**  
  ▪ contusions
  ▪ intracranial hemorrhage (epidural, subdural, intracerebral)

### ASSESSMENT OF BRAIN INJURY

#### History
• pre-hospital status  
• mechanism of injury

#### Physical Examination
• assume C-spine injury until ruled out  
• vital signs  
  ▪ shock (not likely due to isolated brain injury, except in infants)
  ▪ Cushing's response to increasing ICP (bradycardia, hypertension, irregular respirations)
• severity of injury determined by  
  1. LOC  
     ▪ GCS ≤8 intubate, any change in score of 3 or more = serious injury  
     ▪ mild TBI = 13-15, moderate = 9-12, severe = 3-8
  2. pupils: size, anisocoria >1 mm (in patient with altered LOC), response to light
  3. lateralizing signs (motor/sensory)  
     ▪ may become more subtle with increasing severity of injury
• reassess frequently

#### Investigations
• labs: CBC, electrolytes, PT/PTT or INR/PTT, glucose, toxicology screen  
• CT scan (non-contrast) to exclude intracranial mass lesions  
• C-spine imaging, often with CT head and neck to exclude intracranial mass lesions

#### Management
• goal in ED: reduce secondary injury by avoiding hypoxia, ischemia, decreased CPP, seizure

  general
  ▪ ABCs
  ▪ ensure oxygen delivery to brain through intubation and prevent hypercarbia
  ▪ maintain BP (sBP >90)
• treat other injuries
• early neurosurgical consultation for acute and subsequent patient management

  medical management
  ▪ seizure treatment/prophylaxis  
    ▪ benzodiazepines, phenytoin, phenobarbital
    ▪ steroids are of no proven value
  ▪ treat suspected raised ICP  
    ▪ consider if head injury with signs of increased ICP:  
      ▪ raise head of stretcher 20° if patient hemodynamically stable  
      ▪ intubate and hyperventilate (100% O₂) to a pCO₂ of 30-35 mmHg
      ▪ mannitol 1g/kg infused as rapidly as possible (contraindicated in shock and renal failure/anuria)
      ▪ consider paralyzing medications if agitated/high airway pressures
      ▪ maintenance of CPP is critical (CPP=MAP-ICP)

#### Disposition
• neurosurgical ICU admission for severe head injuries (HI)
• in hemodynamically unstable patient with other injuries, prioritize most life-threatening injuries and maintain cerebral perfusion
• for minor head injury not requiring admission, provide 24 h HI protocol to competent caregiver, follow-up with neurology as even seemingly minor HI may cause lasting deficits
Mild Traumatic Brain Injury

Epidemiology
- traumatic brain injury results in 1.7 million deaths, hospitalizations and ED visits each year (US)
- 75% are estimated to be mild TBI; remainder are moderate or severe (see Neurosurgery, NS31)
- highest rates in children 0-4 yr, adolescents 15-19 yr and elderly >65 yr

Clinical Features
- somatic: headache, sleep disturbance, nausea, vomiting, blurred vision
- cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
- emotion and behaviour: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils

Etiology
- falls, motor vehicle and traffic accidents, struck by an object, assault, sports

Investigations
- neuro exam
- concussion recognition tool (see thinkfirst.ca)
- imaging – CT as per Canadian CT Head Rules, or MRI if worsening symptoms despite normal CT

Treatment
- close observation and follow-up; patients at risk of intracranial complications [give appropriate discharge instructions to patient and family] watch for changes to clinical features above, and if change, return to ER
- hospitalization with normal CT (GCS <15, seizures, bleeding diathesis), or with abnormal CT
- early rehabilitation to maximize outcomes
- pharmacological management of pain, depression, headache
- follow Return to Play guidelines: Cantu, Colorado Medical Society, American Academy of Neurology, 2008 Consensus Statement on Concussion in Sports – no data on superiority

Prognosis
- most recover with minimal treatment
  - athletes with previous concussion are at increased risk of cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema or permanent impairment

Spine and Spinal Cord Trauma

- assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck or back
- spinal immobilization (cervical collar, spine board during patient transport only) must be maintained until spinal injury has been ruled out (Figure 2)
- vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude spinal injury
- cord may be injured despite normal C-spine x-ray (SCIWORA = spinal cord injury without radiologic abnormality)
- injuries can include: complete/incomplete transection, cord edema, spinal shock

History
- mechanism of injury, previous deficits, SAMPLE
- neck pain, paralysis/weakness, paresthesia

Physical Exam
- ABCs
- abdo: ecchymosis, tenderness
- neuro: complete exam, including mental status
- spine: maintain neutral position, palpate C-spine; logroll, then palpate T-spine and L-spine spine; assess rectal tone
  - when palpating assess for tenderness, muscle spasm, bony deformities, step-off and spinous process mal-alignment
- extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Investigations
- labs: CBC, electrolytes, creatinine, glucose, coagulation profile, cross and type, toxicology screen
- imaging
  - full C-spine x-ray series for trauma (AP, lateral, odontoid)
  - thoracolumbar x-rays
  - AP and lateral views
  - indications:
    - patients with C-spine injury
    - unconscious patients (with appropriate mechanism of injury)
    - patients with neurological symptoms or findings

Epidemiology

- falls, motor vehicle and traffic accidents, struck by an object, assault, sports

Investigations

- neuro exam
- concussion recognition tool (see thinkfirst.ca)
- imaging – CT as per Canadian CT Head Rules, or MRI if worsening symptoms despite normal CT

Treatment

- close observation and follow-up; patients at risk of intracranial complications [give appropriate discharge instructions to patient and family] watch for changes to clinical features above, and if change, return to ER
- hospitalization with normal CT (GCS <15, seizures, bleeding diathesis), or with abnormal CT
- early rehabilitation to maximize outcomes
- pharmacological management of pain, depression, headache
- follow Return to Play guidelines: Cantu, Colorado Medical Society, American Academy of Neurology, 2008 Consensus Statement on Concussion in Sports – no data on superiority

Prognosis

- most recover with minimal treatment
  - athletes with previous concussion are at increased risk of cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema or permanent impairment

Spine and Spinal Cord Trauma

- assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck or back
- spinal immobilization (cervical collar, spine board during patient transport only) must be maintained until spinal injury has been ruled out (Figure 2)
- vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude spinal injury
- cord may be injured despite normal C-spine x-ray (SCIWORA = spinal cord injury without radiologic abnormality)
- injuries can include: complete/incomplete transection, cord edema, spinal shock

History

- mechanism of injury, previous deficits, SAMPLE
- neck pain, paralysis/weakness, paresthesia

Physical Exam

- ABCs
- abdo: ecchymosis, tenderness
- neuro: complete exam, including mental status
- spine: maintain neutral position, palpate C-spine; logroll, then palpate T-spine and L-spine spine; assess rectal tone
  - when palpating assess for tenderness, muscle spasm, bony deformities, step-off and spinous process mal-alignment
- extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Investigations

- labs: CBC, electrolytes, creatinine, glucose, coagulation profile, cross and type, toxicology screen
- imaging
  - full C-spine x-ray series for trauma (AP, lateral, odontoid)
  - thoracolumbar x-rays
  - AP and lateral views
  - indications:
    - patients with C-spine injury
    - unconscious patients (with appropriate mechanism of injury)
    - patients with neurological symptoms or findings
• patients with deformities that are palpable when patient logroll
• patients with back pain
• patients with bilateral calcaneal fractures (due to fall from height)
• concurrent burst fractures of the lumbar or thoracic spine in 10% (T11-L2)
• consider CT (for subtle bony injuries), MRI (for soft tissue injuries) if appropriate

Management of Cord Injury
• immobilize
• evaluate ABCs
• treat shock (maintain SBP >100 mmHg)
• insert NG and Foley catheter
• high dose steroids: methylprednisolone 30 mg/kg bolus, then 5.4 mg/kg/h drip, start within 6-8 h of injury (controversial and recently has less support)
• complete imaging of spine and consult spine service if available
• continually reassess high cord injuries as edema can travel up cord
• if cervical cord lesion, watch for respiratory insufficiency
  • low cervical transection (C5-T1) produces abdominal breathing (phrenic innervation of diaphragm still intact)
  • high cervical cord injury (above C4) may require intubation and ventilation
• beware of hypotension (neurogenic shock)
• treatment: warm blanket, Trendelenberg position (occasionally), volume infusion, consider vasopressors

Approach to C-Spine X-Rays
• 3-view C-spine series is the screening modality of choice
  1. lateral C1-T1 ± swimmer’s view (Figure 3, see Table 6 for interpretation)
  • lateral view is best, identifies 90-95% of injuries
  2. odontoid view (open mouth or oblique submental view) (see Figure 4)
  • examine the dens for fractures
  • if unable to rule out fracture, repeat view or consider CT or plain film tomography
  • examine lateral aspects of C1 and spacing relative to C2
  3. AP view
  • alignment of spinous processes in the midline
  • spacing of spinous processes should be equal
  • check vertebral bodies and facet dislocations

Figure 2. Approach to clearing the C-spine

Can Clear C-spine if:
• no posterior midline cervical tenderness
• no evidence of intoxication
• oriented to person, place, time and event
• no focal neurological deficits
• no painful distracting injuries (e.g. long bone fracture)

Figure 3. Lines of contour on a lateral C-spine x-ray

Prevertebral soft tissue swelling is only 49% sensitive for injury.
Supine Oblique Views
- rarely used
- better visualization of posterior element fractures (lamina, pedicle, facet joint)
- good to assess patency of neural foramina
- can be used to visualize the C7-T1 junction

Table 6. Interpretation of Lateral View: The ABCS

A Adequacy and Alignment
- Must see C1 to C7-T1 junction; if not, downward traction of shoulders, swimmer’s view, bilateral supine obliques, or CT scan needed
- Lines of contour – in children < 8 yr of age: can see physiologic subluxation of C2 on C3, and C3 on C4, but the spino-laminar line is maintained
- Fanning of spinous processes – suggests posterior ligamentous disruption
- Widening of facet joints
- Check atlanto-occipital joint:
  - Line extending inferiorly from clivus should transect odontoid
  - Atlanto-axial articulation – widening of predental space (normal: < 3 mm in adults, < 5 mm in children) indicates injury of C1 or C2
  - Spino-laminal line is maintained

B Bones
- Height, width and shape of each vertebral body
- Pedicles, facets, and laminae should appear as one – doubling suggests rotation

C Cartilage
- Intervertebral disc spaces – wedging anteriorly or posteriorly suggests vertebral compression

S Soft Tissues
- Widening of retropharyngeal (normal: < 7 mm at C1-4, may be wide in children < 2 yr on expiration) or retrotracheal spaces (normal: < 22 mm at C6-T1, < 14 mm in children < 5 yr)

Sequelles of C-spine Fractures
- see Neurosurgery. NS 32
- acute phase of SCI
  - spinal shock: absence of all voluntary and reflex activity below level of injury
  - decreased reflexes, no sensation, flaccid paralysis below level of injury, lasting days to months
- neurogenic shock: loss of vasomotor tone, SNS tone
  - watch for: hypotension (lacking SNS), bradycardia (unopposed PNS), poikilothermia (lacking SNS so no shunting of blood from extremities to core)
  - occurs within 30 min of SCI at level T6 or above, lasting up to 6 wk
  - provide airway support, fluids, atropine (for bradycardia), vasopressors for BP support
- chronic phase of SCI
  - autonomic dysreflexia: in patients with an SCI at level T6 or above
  - signs and symptoms: pounding headache, nasal congestion, feeling of apprehension or anxiety, visual changes, dangerously increased sBP and dBP
  - common triggers
    - GU causes: bladder distention, urinary tract infection, and kidney stones
    - GI causes: fecal impaction or bowel distension
  - treatment: monitoring and controlling BP, prior to addressing causative issue

Chest Trauma
- two types: those found and managed in 1º survey and those found and managed in 2º survey (see Tables 7 and 8)

Table 7. Life-Threatening Chest Injuries Found in 1º Survey

<table>
<thead>
<tr>
<th>Physical Exam</th>
<th>Investigations</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Airway Obstruction</strong></td>
<td>Anxiety, stridor, hoarseness, altered mental status, Aprexia, cyanosis</td>
<td>Do not wait for ABG to intubate</td>
</tr>
<tr>
<td><strong>Tension Pneumothorax</strong></td>
<td>Respiratory distress, tachycardia, distended neck veins, cyanosis, asymmetry of chest wall motion</td>
<td>Non-radiographic diagnosis</td>
</tr>
</tbody>
</table>

Figure 4. C-spine x-ray; odontoid view
- In contrast to neurogenic shock, hypovolemic shock has hypotension and tachycardia.
- Autonomic dysreflexia – a life threatening elevation of BP with SCI at or above T6.
- 20% of C-spine fractures are accompanied by other spinal fractures, so ensure thoracic and lumbar spine x-rays are normal before proceeding to OR.
- Trauma to the chest accounts for 50% of trauma deaths.
- 80% of all chest injuries can be managed non-surgically with simple measures such as intubation, chest tubes, and pain control.
- 3-way Seal for Open Pneumothorax (i.e. sucking chest wound): Allows air to escape during the expiratory phase (so that you don’t get a tension pneumothorax) but seals itself to allow adequate breaths during the inspiratory phase.
- Pulsus Paradoxus: a drop in BP of > 10 mmHg with inspiration. Recall that BP normally drops with inspiration, but what’s “paradoxical” about this is that it drops more than it should.
Airway Injuries

- Penetrating Neck Trauma
  - DON'T: Clamp structures (can damage nerves)
  - Probe
  - Insert NG tube (leads to bleeding)
  - Remove weapon/impaled object

Ruptured diaphragm is more often diagnosed on the left side, as liver conceals right side defect.

Aortic Tear: ABC WHITE
- x-ray features of Aortic tear depressed left mainstem Bronchus pleural
- Wide mediastinum (most consistent)
- Hemorrhage
- Indirect aortic knuckle
- Tracheal deviation to right side
- Esophagus (NG tube) deviated to right

(Note: present in 85% of cases, but cannot rule out)

If Penetrating Neck Trauma Present, DON'T:
- Clamp structures (can damage nerves)
- Probe
- Insert NG tube (leads to bleeding)
- Remove weapon/impaled object

Other Potentially Life-Threatening Injuries Related to the Chest

Penetrating Neck Trauma
- includes all penetrating trauma to the three zones of the neck (Figure 5)
- management: injuries deep to platysma require further evaluation by angiography, contrast CT or surgery
- do not explore penetrating neck wounds except in the OR

Airway Injuries
- always maintain a high index of suspicion

<td>• Usually penetrating trauma (pain out of proportion to degree of injury)</td>
<td>• CXR: mediastinal air (not always)</td>
</tr>
<tr>
<td>Aortic Tear</td>
<td>• 90% tear at subclavian (near ligamentum arteriosum), most die at scene</td>
<td>• Sudden high speed deceleration (e.g. MVC, fall, airplane crash), complaints of chest pain, dyspnea, hoarseness (frequently absent)</td>
</tr>
<tr>
<td>Blunt Myocardial Injury (rare)</td>
<td>• Blunt trauma to chest (usually in setting of multi-system trauma and therefore difficult to diagnose)</td>
<td>• Physical examination: overlying injury, e.g. fractures, chest wall contusion</td>
</tr>
</tbody>
</table>

HOT and FAT CHEST
- Hemothorax*
- Open pneumothorax
- Tension pneumothorax*
- Flail chest
- Airway obstruction
- Tamponade*

Contusion: pulmonary, myocardial
Hernia: traumatic, diaphragmatic
Esophageal perforation
Tracheobronchial disruption/ Traumatic injury/Thoracic Aorta Rupture* *Rapidly Life Threatening

DDx of Life Threatening Chest Injuries

Zone III: Superior aspect of neck
Zone II: Midportion of neck (cricord to the angle of mandible)
Zone I: Base of neck (thoracic inlet to cricoid cartilage)
larynx
- history: strangulation, direct blow, blunt trauma, any penetrating injury involving platysma
- triad: hoarseness, subcutaneous emphysema, palpable fracture crepitus
- other symptoms: hemothysis, dyspnea, dysphonia
- investigations: CXR, CT scan, arteriography (if penetrating)
- management
  - airway: manage early because of edema
  - C-spine may also be injured, consider mechanism of injury
  - surgical: tracheotomy vs. repair

trachea/bronchus
- frequently missed
- history: deceleration, penetration, increased intra-thoracic pressure; complaints of dyspnea, hemothysis
- examination: subcutaneous air, Hamman’s sign (crunching sound synchronous with heart beat)
- CXR: mediastinal air, persistent pneumothorax or persistent air leak after chest tube inserted for pneumothorax
- management: surgical repair if >1/3 circumference

Abdominal Trauma
- two mechanisms
  - blunt: usually causes solid organ injury (spleen = most common, liver = 2nd)
  - penetrating: usually causes hollow organ injury or liver injury (most common)

BLUNT TRAUMA
- results in two types of hemorrhage: intra-abdominal and retroperitoneal
- adopt high clinical suspicion of bleeding in multi-system trauma

History
- mechanism of injury, SAMPLE history

Physical Exam
- often unreliable in multi-system trauma, wide spectrum of presentations
  - slow blood loss not immediately apparent
  - other injuries may mask symptoms
  - serial examinations are required
- abdomen
  - inspect: contusions, abrasions, seatbelt sign, distention
  - auscultate: bruits, bowel sounds
  - palpate: tenderness, rebound tenderness, rigidity, guarding
  - DRE: rectal tone, blood, bone fragments, prostate location
  - placement of NG, Foley catheter should be considered part of the abdominal exam
- other systems to assess: cardiovascular, respiratory (possibility of diaphragm rupture), genitourinary, pelvis, back/neurological

Investigations
- labs: CBC, electrolytes, coagulation, cross and type, glucose, creatinine, CK, lipase, amylase, liver enzymes, ABG, blood EtOH, β-hCG, U/A, toxicology screen
- imaging: see Table 9

<table>
<thead>

imaging must be done if
- equivocal abdominal examination, suspected intra-abdominal injury or distracting injuries
- multiple trauma patient resulting in unreliable physical exam (altered sensorium, secondary to drugs, alcohol, head trauma, or distracting injury; spinal cord injury resulting in abdominal anesthesia)
- unexplained shock/hypotension
- multiple trauma patients who must undergo general anesthesia for orthopedic, neurosurgical, or other injuries
- fractures of lower ribs, pelvis, spine
- positive FAST

**Management**
- general: ABCs, fluid resuscitation and stabilization
- surgical: watchful waiting vs. laparotomy
- solid organ injuries: decision based on hemodynamic stability, not the specific injuries
- hemodynamically unstable or persistently high transfusion requirements: laparotomy
- hollow organ injuries: laparotomy
- even if low suspicion of injury: admit and observe for 24 h

**Penetrating Trauma**
- high risk of gastrointestinal perforation and sepsis
- history: size of blade, calibre/distance from gun, route of entry
- local wound exploration under direct vision may determine lack of peritoneal penetration (not reliable in inexperienced hands) with the following exceptions:
  - thoracoabdominal region (may cause pneumothorax)
  - back or flanks (muscles too thick)

**Management**
- general: ABCs, fluid resuscitation and stabilization
- gunshot wounds ➔ always require laparotomy

**Genitourinary Tract Injuries**

- see Urology, U32

**Etiology**
- blunt trauma: often associated with pelvic fractures
  - upper tract
    - renal
      - contusions (minor injury – parenchymal ecchymoses with intact renal capsule)
      - parenchymal tears/laceration: non-communicating (hematoma) vs. communicating (urine extravasation, hematuria)
    - ureter: rare, at uretero-pelvic junction
  - lower tract
    - bladder
      - extraperitoneal rupture of bladder from pelvic fracture fragments
      - intraperitoneal rupture of bladder from trauma and full bladder
    - urethra
      - posterior urethral injuries: MVCs, falls, pelvic fractures
      - anterior urethral injuries: blunt trauma to perineum, straddle injuries/direct strikes
  - external genitalia
  - penetrating trauma
    - damage to: kidney, bladder, ureter (rare), external genitalia
  - acceleration/deceleration injury
    - renal pedicle injury: high mortality rate (laceration and thrombosis of renal artery, renal vein, and their branches)
  - iatrogenic
    - ureter and urethra (from instrumentation)

**History**
- mechanism of injury
- hematuria (microscopic or gross), blood on underwear
- dysuria, urinary retention
- history of hypotension
Physical Examination
- abdominal pain, flank pain, costovertebral angle (CVA) tenderness, upper quadrant mass, perineal lacerations
- DRE: sphincter tone, position of prostate, presence of blood
- scrotum: ecchymoses, lacerations, testicular disruption, hematomas
- bimanual exam, speculum exam
- extraperitoneal bladder rupture: pelvic instability, suprapubic tenderness from mass of urine or extravasated blood
- intraperitoneal bladder rupture: acute abdomen
- urethral injury: perineal ecchymosis, scrotal hematoma, blood at penile meatus, high riding prostate, pelvic fractures

Investigations
- urethra: retrograde urethrography
- bladder: urinalysis, CT scan, urethrogram, ± retrograde cystoscopy, ± cystogram (distended bladder + post-void)
- ureter: retrograde ureterogram
- renal: CT scan (best, if hemodynamically stable), intravenous pyelogram (IVP)

Management
- urology consult
- renal
  - minor injuries: conservative management
    - bedrest, hydration, analgesia, antibiotics
  - major injuries: admit
    - conservative management with frequent reassessments, serial urinalysis, ± re-imaging
    - surgical repair (exploration, nephrectomy): e.g. hemodynamically unstable or continuing to bleed >48 h, major urine extravasation, renal pedicle injury, all penetrating wounds and major lacerations, infections, renal artery thrombosis
- ureter
  - uretero-uretostomy
- bladder
  - extraperitoneal
    - minor rupture: Foley drainage x 10-14 d
  - major rupture: surgical repair
  - intraperitoneal
    - drain abdomen and surgical repair
- urethra
  - anterior: conservative, if cannot void → Foley or suprapubic cystostomy and antibiotics
  - posterior: suprapubic cystostomy (avoid catheterization) ± surgical repair

Orthopedic Injuries
- see Orthopedics (Shoulder OR10, Knee, OR29 Wrist OR19, Ankle OR35)

Goals of ED Treatment
- diagnose potentially life/limb threatening injuries
- reduce and immobilize fractures (cast/splint) as appropriate
- provide adequate pain relief
- arrange proper follow-up if necessary

History
- use SAMPLE
- mechanism of injury may be very important

Physical Examination
- look (inspection): "SEADS" Swelling, Erythema, Atrophy, Deformity, Skin changes (e.g. bruises)
- feel (palpation): all joints/bones – local tenderness, swelling, warmth, crepitus, joint effusions, subtle deformity
- move: joints affected plus those above and below injury – active ROM preferred to passive
- neurovascular status: distal to injury (before and after reduction)
LIFE AND LIMB THREATENING INJURIES

Table 10. Life and Limb Threatening Orthopedic Injuries

<table>
<thead>
<tr>
<th>Life Threatening Injuries (usually blood loss)</th>
<th>Limb Threatening Injuries (usually interruption of blood supply)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Major pelvic fractures</td>
<td>Fracture/dislocation of ankle (talar AVN)</td>
</tr>
<tr>
<td>Traumatic amputations</td>
<td>Crush injuries</td>
</tr>
<tr>
<td>Massive long bone injuries (beware of fat emboli)</td>
<td>Compartment syndrome</td>
</tr>
<tr>
<td>Vascular injury proximal to knee/elbow</td>
<td>Open fractures</td>
</tr>
<tr>
<td></td>
<td>Dislocations of knee/hip</td>
</tr>
<tr>
<td></td>
<td>Fractures above knee/elbow</td>
</tr>
</tbody>
</table>

Open Fractures
- communication between fracture site and external surface of skin – increased risk of osteomyelitis
- remove gross debris, irrigate, cover with sterile dressing – formal irrigation and debridement often done in the OR
- control bleeding with pressure (no clamping)
- splint
- antibiotics (1st generation cephalosporin and aminoglycoside) and tetanus prophylaxis
- must secure definitive surgical care within 6-8 h

Vascular Injuries
- realign limb/apply longitudinal traction and reassess pulses (e.g. Doppler probe)
- surgical consult
- direct pressure if external bleeding

Compartment Syndrome
- increased interstitial pressure in an anatomical “compartment” (forearm, calf) with little room for expansion, resulting in decreased perfusion and potential muscle/nerve necrosis
- clinical diagnosis: maintain a high index of suspicion
  - pain out of proportion to the injury
  - pain worse with passive stretch
  - look for “the 6 Ps” (see side bar)
- requires prompt decompression: remove constrictive casts, dressings; fasciotomy may be needed emergently

UPPER EXTREMITY INJURIES
- anterior shoulder dislocation
  - axillary nerve (lateral aspect of shoulder) and musculocutaneous nerve (extensor aspect of forearm) at risk
  - seen on lateral view: humeral head anterior to glenoid
    - reduce (traction, scapular manipulation), immobilize in internal rotation, repeat x-ray, out-patient follow-up with ortho
    - with forceful injury, look for fracture
  - Colles’ fracture (Figure 6)
    - distal radius fracture with dorsal displacement from Fall On an Outstretched Hand (FOOSH)
    - AP film: shortening, radial deviation, radial displacement
    - lateral film: dorsal displacement, volar angulation
    - reduce, immobilize with splint, out-patient follow-up with ortho or immediate orthopedic referral if complicated fracture
    - if involvement of articular surface, emergent orthopedic referral
  - scaphoid fracture (see Figure 7 for review of carpal bones)
    - tenderness in anatomical snuff box, pain on scaphoid tubercle, pain on axial loading of thumb
    - negative x-ray; thumb spica splint, re-x-ray in 1 wk ± bone scan
    - positive x-ray; thumb spica splint x 6-8 wk, re-x-ray in 2 wk
    - risk of AVN of scaphoid if not immobilized
    - outpatient ortho follow-up

LOWER EXTREMITY INJURIES
- ankle and foot fractures
  - see Ottawa Ankle and Foot Rules (Figure 8)
- knee injuries
  - see Ottawa Knee Rules (Figure 9)
• avulsion of the base of 5th metatarsal
  - occurs with inversion injury
  - supportive tensor or below knee walking cast for 3 wk
• calcaneal fracture
  - associated with fall from height
  - associated injuries may involve ankles, knees, hips, pelvis, lumbar spine

A knee x-ray examination is required only for acute injury patients with one or more of:
- Age 55 yrs or older
- Tenderness at head of fibula
- Isolated tenderness of patella
- Inability to flex to 90°
- Inability to bear weight both immediately and in the emergency department

Wound Management

Goals of ED Treatment
- identify injuries and stop any active bleeding – direct pressure
- manage pain
- wound examination and exploration (history and physical)
- cleansing ± antibiotic and tetanus prophylaxis
- closure and dressing

Tetanus Prophylaxis
- both tetanus toxoid (Td) and immunoglobulin (TIG) are safe in pregnancy

<table>
<thead>

¹ wounds >6 h old, >1 cm deep, puncture wounds, avulsions, wounds resulting from missiles, crush wounds, burns, frostbite, wounds contaminated with dirt, feces, soil, or saliva
² 0.5 mL IM tetanus and diphtheria toxoids (Td), adsorbed
³ tetanus immune globulin (TIG), 250 units deep IM

Source: MMWR 2001;50;418-427; MMWR 1991;40:1-52
Bruises

- non-palpable = ecchymosis
- palpable collection (not swelling) = hematoma following blunt trauma
- assess for coagulopathy (e.g. liver disease), anticoagulant use

Abrasions

- partial to full thickness break in skin
- management
  - clean thoroughly, ± local anesthetic, with brush to prevent foreign body impregnation
  - antiseptic ointment (Polysporin® or Vaseline®) for 7 d for facial and complex abrasions
  - tetanus prophylaxis (Table 11)

Lacerations

- see also Plastic Surgery, PL8
- consider every structure deep to a laceration injured until proven otherwise
- in hand injury patients, include the following in history: handedness, occupation, mechanism of injury, previous history of injury
- physical exam
  - think about underlying anatomy
  - examine tendon function actively against resistance and neurovascular status distally
  - clean and explore under local anesthetic; look for partial tendon injuries
  - x-ray or ultrasound wounds if a foreign body is suspected (e.g. shattered glass) and not found when exploring wound (remember: not all foreign bodies are radiopaque), or if suspect intra-articular involvement
- management
  - disinfect skin/use sterile techniques
  - irrigate copiously with normal saline
  - analgesia ± anesthesia
  - maximum dose of lidocaine:
    - 7 mg/kg with epinephrine
    - 5 mg/kg without epinephrine
  - in children, topical anesthetics such as LET (lidocaine, epinephrine and tetracaine) and in selected cases a short-acting benzodiazepine (midazolam or other agents) for sedation and amnesia are useful
  - secure hemostasis
  - evacuate hematomas, debride non-viable tissue, remove hair and foreign bodies
  - ± prophylactic antibiotics (consider for animal/human bites, intraoral lesion or puncture wounds to the foot)
  - take into account patient and wound factors when considering suturing
  - secure hemostasis
  - evacuate hematomas, debride non-viable tissue, remove hair and foreign bodies
  - ± prophylactic antibiotics (consider for animal/human bites, intraoral lesion or puncture wounds to the foot)
  - x-ray or ultrasound wounds if a foreign body is suspected (e.g. shattered glass) and not found when exploring wound (remember: not all foreign bodies are radiopaque), or if suspect intra-articular involvement
  - advise patient when to have sutures removed
  - cellulitis and necrotising fasciitis, see Plastic Surgery, PL14

Trauma in Pregnancy

- priorities: airway, breathing, circulation

Hemodynamic Considerations (changes that mimic shock)

- near term, inferior vena cava compression in the supine position can decrease cardiac output by 30-40% (see Maternal Physiology, Obstetrics, OB3)
  - use left lateral decubitus (LLD) positioning or hip bolster to alleviate compression and increase blood return if BP is low
- BP drops 5-15 mmHg systolic in 2nd trimester, increases to normal by term
- HR increases 15-20 beats per minute by 3rd trimester

Blood Considerations

- physiologic macrocytic anemia of pregnancy (Hb 100-120 g/L)
- WBC increases to a high of 20,000
- blood volume increase in pregnancy up to 45% (change can mask hypovolemic shock)

Shock

- pregnant patients may lose 35% of blood volume without typical signs of shock (i.e. tachycardia, hypotension)
- the fetus may be in “shock” due to contraction of the uteroplacental circulation
- fetal HR changes are an early warning of maternal circulatory compromise

Management Differences

- place bolster under right hip to stop inferior vena cava compression
- fetal monitoring (HR and fetal movements, continuous tocographic monitoring if viable fetus (>20 wk)
- early obstetrical consult
- do not avoid necessary imaging, but shield as much as possible
- consider need for RhoGAM® if mother Rh negative

High Risk Factors for Infection

- Puncture wounds
- Crush injuries
- Wounds greater than 12 h old
- Hand or foot wounds, wounds near joints
- Immune compromised patient
- Patient age greater than 50 yr
- Prosthetic joints or valves (risk of endocarditis)

Early wound irrigation and debridement are the most important factors in decreasing infection.

Since cellulitis can cause edema, remember to elevate the leg to decrease discomfort. Treat with antibiotics, analgesics and close follow-up.

The best treatment for the fetus is effective treatment of the mother.

- Primary survey: focus on mother
- Secondary survey: detailed assessment of mother + acquire info about fetus (Hx, fetal monitoring, etc.)
Approach to Common ER Presentations

Abdominal Pain

Rule Out Life-Threatening Causes
- CVS: MI, aortic dissection (tearing pain), ruptured AAA
- GI: perforated viscus, hepatic/splenic injury, ischemic bowel (diffuse pain)
- gynecologic: ectopic pregnancy

Additional Differential Diagnosis
- GI: appendicitis, diverticulitis, bowel obstruction, hepatitis, cholecystitis, pancreatitis
- urinary: pyelonephritis, ureteral calculi, cystitis
- gynecal:
  - female: tubo-ovarian abscess, ovarian torsion, ovarian cyst, salpingitis, pelvic inflammatory disease (PID), endometriosis
  - male: testicular torsion, epididymitis, prostatitis
- other: diabetic ketoacidosis (DKA), herpes zoster virus (HZV), intra-abdominal abscess, pneumonia, lead poisoning, porphyria, sickle cell crisis, psychiatric

History
- pain: OPQRST
- broad differential, including GU, gyn, GI, respiratory, and CV systems
- recent/remote abdominal trauma/surgeries

Physical Examination
- vitals, abdominal (including DRE, CVA tenderness), pelvic/genital, respiratory, and CVS as indicated by history

Investigations
- do not delay consultation if patient unstable
- CBC, electrolytes, glucose, BUN/creatinine, U/A, ± LFTs, lipase (if upper abdominal pain)
- ± others if indicated: β-hCG, ECG, troponins
- AXR: look for calcifications, free air, gas pattern, air fluid levels
- CXR upright: look for pneumoperitoneum (free air under diaphragm)
- U/S: biliary tract, ectopic pregnancy, AAA, free fluid
- CT: trauma, AAA, pancreatitis, nephro/uro lithiasis, appendicitis and diverticulitis

Management
- NPO, IV, NG tube, analgesics, consider antibiotics and anti-emetics
- growing evidence that small amounts of opioid analgesics improve diagnostic accuracy of physical exam of surgical abdomen
- consult as necessary: general surgery, vascular, gynecology, etc.

Disposition
- admission: surgical abdomen, workup of significant abnormal findings, need for IV antibiotics or pain control
- discharge: patients with a negative lab and imaging workup who improve clinically during their stay; instruct the patient to return if severe pain, fever, or persistent vomiting develop

Acute Pelvic Pain

Etiology
- gynecological
  - ovaries: ruptured ovarian cysts (most common cause of pelvic pain), ovarian abscess, ovarian torsion (rare, 50% will have ovarian mass)
  - fallopian tubes: salpingitis (STI), tubal abscess, hydrosalpinx
  - uterus: leiomyomas (uterine fibroids) – especially with torsion of a pedunculated fibroid or in pregnant patient (degeneration), PID, endometriosis
  - other: ectopic pregnancy (ruptured/expanding/leaking), spontaneous abortion (threatened or incomplete), dysmenorrhea and endometriosis
- non-gynecological
  - GI: appendicitis, constipation, bowel obstruction, gastroenteritis, diverticulitis, IBD, IBS
  - GU: cystitis, pyelonephritis, ureteric stone
  - other: porphyria, abdominal angina, aneurysm, hernia, zoster

Red Flags
- Unstable vital signs
- Fever
- Signs/symptoms of shock
- Rapid onset severe pain

Be vigilant in those at extremes of ages (very young, elderly) as they often present atypically!

Abdominal Assessment in all 4 Quadrants

If elevated AST and ALT: think hepatocellular injury
AST > ALT: alcohol – related
ALT > AST: viral, drug, toxin
If elevated ALP and GGT: “think biliary tree” stones

Old age, pregnancy (T3), and chronic corticosteroid use can blunt peritoneal findings, so have increased suspicion of intrabdominal process in these individuals!

Gynecological Causes of Pelvic Pain:
- Ovarian cyst
- Dysmenorrhea
- Mittelschmerz
- Endometriosis
- Ovarian torsion
- Uterine fibroids/neoplasm
- Adnexal neoplasm
- PID + cervicitis

Unstable patients should not be sent for imaging.

All women of childbearing age are assumed to be pregnant. Every pregnancy is potentially ectopic. A β-hCG must be obtained!
History and Physical Exam
- pain: OPQRST
- associated symptoms: vaginal bleeding, bowel or bladder symptoms, radiation
- vitals
- gynecological exam: assess for cervical motion tenderness = chandelier sign (suggests PID)
- abdominal exam

Investigations
- bloodwork
  - β-hCG for all women of childbearing age
  - CBC and differential, electrolytes, glucose, BUN/Cr, G&S, PTT/INR
- imaging
  - pelvic and abdominal U/S: evaluate adnexa, look for free fluid in the pelvis or masses, evaluate thickness of endometrium, confirm intrauterine pregnancy if β-hCG positive
  - doppler flow studies for ovarian torsion

Management
- general: analgesia, determine if admission and consults needed
  - gynecology consult if history and physical suggestive of serious cause
  - other consults as indicated
- specific:
  - ovarian cysts
    - unruptured or ruptured and hemodynamically stable: analgesia and follow-up
    - ruptured with significant hemoperitoneum: may require surgery
  - ovarian torsion: surgical detorsion or removal of ovary
  - uncomplicated leiomyomas, endometriosis and secondary dysmenorrhea can usually be treated on an outpatient basis, discharge with gynecology follow-up
  - PID: requires broad spectrum antibiotics

Disposition
- admission: patients requiring surgery, IV antibiotics/pain management
- discharge: negative workup and resolving symptoms; give clear instructions for appropriate follow-up

Altered Level of Consciousness (LOC)

Definitions
- altered mental status: collective, non-specific term referring to change in cognitive function, behaviour, or attentiveness, including:
  - delirium (see Psychiatry, PS19)
  - dementia (see Psychiatry, PS20)
  - lethargy: state of decreased awareness and alertness (patient may appear wakeful)
  - stupor: unresponsiveness but aroused
  - coma: a sleep-like state, not arousable to consciousness
- use the GCS to evaluate LOC (see Initial Patient Assessment/Management, ER2)

![Figure 10. Etiology of coma](Image)
MANAGEMENT OF ALTERED LOC

History
- obtain collateral from family, friends, police, paramedics, old chart, etc.
- onset and progression
  - abrupt onset suggests CNS hemorrhage/ischemia or cardiac cause
  - progression over hours to days suggests progressive CNS lesion or toxic/metabolic cause
- preceding events
  - it is essential to determine patient's baseline LOC preceding deterioration
  - antecedent trauma, seizure activity, fever
  - past medical history (e.g. similar episode, depression, overdose)

Physical Examination
- ABCs, vitals including temperature, cardiac, chest, respiratory, abdominal exam, and the "five Ns" (see sidebar)
- complete neuro exam, in particular examination of the eyes (pupil size and reactivity), look for MedicAlert® bracelet

Investigations
- bloodwork
  - rapid blood sugar, CBC, electrolytes, Cr, BUN, LFTs, glucose, serum osmolality, VBG, PT/PTT/INR, troponins
  - serum EtOH, acetaminophen and salicylate levels
- imaging
  - CT head
- other tests
  - ECG, U/A, UTox

Diagnosis
- administer appropriate universal antidotes
  - thiamine 100 mg IV if history of EtOH or patient looks malnourished
  - one ampule D50W IV if low blood sugar on finger-prick
  - naloxone 0.4-2 mg IV or IM if opiate overdose suspected
- distinguish between structural and toxic-metabolic coma
  - structural coma
    - pupils, extraocular movements and motor findings, if present, are usually asymmetric
    - look for focal or lateralizing abnormalities
  - toxic-metabolic coma
    - dysfunction at lower levels of the brainstem (e.g. caloric unresponsiveness)
    - respiratory depression in association with an intact upper brainstem (e.g. equal and reactive pupils; see exceptions in Table 12)
    - extraocular movements and motor findings are symmetric or absent
- essential to re-examine frequently – status can change rapidly
- diagnosis may become apparent only with the passage of time
  - delayed deficit after head trauma suggestive of epidural hematoma (characteristic "lucid interval")

</table>

Disposition
- admission: if ongoing decreased LOC; admit to service based on tentative diagnosis or transfer patient if appropriate level of care not available
- discharge: readily reversible alteration of LOC; ensure adequate follow-up care available

Chest Pain

Rule Out Life-Threatening Causes
- CVS: acute coronary syndrome, pericarditis, cardiac tamponade, aortic dissection
- respiratory: pulmonary embolism (PE), pneumothorax (tension or spontaneous)
- GI: esophageal rupture, pneumomediastinum
Additional Differential Diagnosis
- cardiac: stable angina
- respiratory: pneumonia
- GI: peptic ulcer disease (PUD), pancreatitis, cholecystitis, esophagitis, reflux, esophageal spasm
- MSK: rib fractures, costochondritis, zoster, etc.
- psychogenic/anxiety (diagnosis of exclusion)

Initial Resuscitation and Management
- O₂, IV, cardiac monitoring, CXR (portable if unstable), ECG

History
- must evaluate cardiac risk factors (see TIMI Score, Cardiology, C24)
- classic presentations (but presentation seldom classic)
  - aortic dissection: syncope with sudden severe tearing pain, often radiating to back, ± focal
    pain/neurologic loss in extremities secondary to major vessel ischemia
  - pulmonary embolism: pleuritic chest pain (75%), dyspnea, anxiety, tachycardia, PERC Score
  - pericarditis: anterior precordial pain, pleuritic, relieved by sitting up and leaning forward
  - acute coronary syndrome (ACS): retrosternal squeezing/pressure pain, radiation to arm/neck, dyspnea, nausea/vomiting, syncope
  - esophageal: frequent heartburn, acid reflux, dysphagia, relief with antacids
- ACS more likely to be atypical in females, diabetics, and >80 yr

Physical Examination
- vitals (BP in both arms, but unreliable indicator of dissection)
- palpate chest wall for tender points; present in 25% of acute MI, but may suggest MSK cause if
  symptoms fully reproduced and all serious etiologies have been ruled out
- cardiac exam, respiratory exam, peripheral vascular exam

Investigations
- bloodwork
  - CBC, electrolytes, BUN/Cr
  - CK-MB: if normal, does not rule out MI
  - troponin I: more sensitive (but positive later than CK-MB; can have false positives in renal
    failure, must follow for 8 h post onset of symptoms)
  - D-dimer: if negative, can rule out PE in low probability patients (see sidebar)
- ECG (see Table 13)
  - always compare with previous
- PE and acute MI may have normal ECG in up to 50% of cases
- consider 15-lead ECG if hypotensive or if ECG shows inferior MI or AV node involvement
- CXR
  - always compare with previous
- PE (see DVT, ER33)
  - 50% completely normal
  - atelectasis, elevated hemidiaphragm, pleural effusion
- aortic dissection (see sidebar ER12 for features)
  - change from previous CXR is the most accurate finding
  - widened mediastinum (most consistent finding)
  - CXR is normal in 20% of thoracic dissections
  - pneumothorax (PTX)
    - may need inspiration and expiration views
  - if large, may see tracheal shift (away from tension PTX, towards a non-tension PTX)
- V/Q scan or CT, venous leg Doppler, required to rule out PE in patients with intermediate or
  high probability (see sidebar for Wells’ Score, E34)

Disposition
- admission and monitoring: patients at risk of developing dysrhythmias
- consult: cardiology for patients with ACS; cardiothoracic surgery for patients with valvular
  lesions, esophageal rupture, or aortic dissection
- discharge: patients with a low probability of life-threatening illness due to resolving symptoms
  and negative workup; instruct the patient to return if they develop SOB or increased chest pain
**ACUTE MYOCARDIAL INFARCTION**

- see Cardiology, C24

**Management**

- immediate stabilization
  - oxygen 4 L/min
  - IV access
  - cardiac monitors
  - STAT ECG
  - cardiac enzymes (CK, troponins)
  - ASA 162-325 mg chewed
  - nitroglycerin 0.3 mg SL q5min x 3 (IV for CHF, HTN, unresolved pain)
  - morphine 2-3 mg IV q5-30min if unresponsive to nitroglycerin
  - low molecular weight heparin 1 mg/kg SC bid (30 mg IV STAT post TNK infusion)
  - thrombolytics (within 30 min) or primary percutaneous coronary intervention (PCI) (within 90 min)
  - agents include rt-PA, streptokinase, and TNK
  - evaluate indications and contraindications prior to use
  - other: antisydrhythms, cardioversion, defibrillation, transthoracic pacing, angioplasty
  - cardiology consult

**Epistaxis**

- see Otolaryngology, OT26
- 90% of nosebleeds stem from the anterior nasal septum (at Kesselbach's plexus located in Little's area)
- can be life-threatening

**Etiology**

- most commonly caused by trauma (digital, blunt, foreign bodies)
- other causes: barometric changes, nasal dryness, chemicals (cocaïne, Otrivin®), or systemic disease (coagulopathies, hypertension, etc.)

**Investigations**

- bloodwork: CBC, PT/PTT (as indicated)
- imaging: x-ray, CT as needed
**Treatment**
- aim is to localize bleeding and achieve hemostasis
- first-aid: ABCs, lean forward, pinch cartilaginous portion of nose for 20 min twice
- assess blood loss: vitals, IV normal saline, cross match 2 units packed RBC if significant
- determine site of bleeding: use topical anaesthetic/vasoconstrictor to facilitate; use nasal speculum and good lighting
- attempt to control the bleeding
  - first line: Otrivin® or cocaine
  - second line: cauterize with silver nitrate (one side of septum only because if both are cauterized this can lead to septal perforation!)
  - if these fail, or if bleeding is posterior → nasal packing (must monitor for complications)
  - if packing fails, consult ENT

**Disposition**
- discharge: discharged upon stabilization and appropriate follow-up; educate patients about prevention (e.g. humidifiers, saline spray, topical ointments, avoiding irritants, managing hypertension)
- admission: severe cases of refractory bleeding

### Headache

#### see also Neurology, N38

#### Etiology
- the common
  - common migraine (no aura)/classic migraine (involves aura)
    - gradual onset, unilateral/bilateral, throbbing
    - nausea/vomiting, photo/phonophobia
    - treatment: analgesics, neuroleptics, vasoactive meds
  - tension/muscular headache
    - never during sleep, gradual over 24 h
    - posterior/occipital
    - increased with stressors
    - treatment: modify stressor, local measures, NSAIDs, tricyclic antidepressants
- the deadly
  - subarachnoid hemorrhage (SAH) (see Neurosurgery, NS18)
    - sudden onset, increased with exertion
    - reaches maximum intensity within minutes, nausea and vomiting, meningeal signs
    - diagnosis: CT, LP (5-10% of patients with SAH have negative initial CT)
      - sensitivity of CT decreases with time and is much less sensitive by 48-72 h
    - management: urgent neurosurgery consult
  - increased ICP
    - worse in morning, when supine or bending down, with cough or Valsalva
    - physical exam: neurological deficits, cranial nerve palsies, papilledema
    - diagnosis: CT scan
    - management: consult neurosurgery
  - meningitis (see Infectious Diseases, ID19)
    - flu-like presentation initially (fever, nausea/vomiting, malaise), meningeal signs, purpuric rash
    - altered LOC and confusion
    - perform CT to rule out increased ICP then do LP for diagnosis
    - treatment: early empiric antibiotics (depending on age group), steroid therapy
  - temporal arteritis (causes great morbidity in terms of blindness) (see Ophthalmology, OP38)
    - unilateral scalp tenderness, jaw claudication, visual disturbances
    - labs: elevated ESR, CRP
    - temporal artery biopsy is gold standard for diagnosis
    - associated with polymyalgia rheumatica
    - treatment: high-dose steroids immediately if suspected

#### Disposition
- admission: if underlying diagnosis is critical or emergent, if there are abnormal neurological findings, if patient is elderly or immunocompromised (atypical presentation), or if pain is refractory to oral medications
- discharge: most patients can be discharged with appropriate analgesia and follow up with their family physician; instruct patients to return for fever, vomiting, neurologic changes, or increasing pain

---

**DDx Subarachnoid Hemorrhage**

**BATS**

- Berry aneurysm
- Arteriovenous malformation/Adult polycystic kidney disease
- Trauma
- Stroke

*Note: up to 5% of patients with subarachnoid hemorrhage have a normal CT scan; if suspect SAH with a negative CT, perform a LP.*

**Meningitis**

*Do not delay IV antibiotics for LP.*
Joint Pain

• see Rheumatology, RH3

Rule Out Life-Threatening Causes
• septic joint (see Orthopedics, OR10)

Differential Diagnosis
• articular pain
  ▪ monoarticular
    • infectious: bacterial, viral, fungal
    • hemarthrosis: trauma/fracture, anticoagulants, bleeding diatheses
    • crystal induced: gout, calcium pyrophosphate deposition, hydroxyapatite
    • inflammatory: seropositive, seronegative
    • neoplasm
    • degenerative: osteoarthritis
  ▪ polyarticular
    • infectious: Lyme disease, bacterial endocarditis, septicemia, gonococcus, viral
    • post-infectious: rheumatic fever, reactive arthritis, enteric infections
    • inflammatory: seropositive, seronegative
    • degenerative: osteoarthritis
• non-articular
  ▪ musculoskeletal
    • localized: tendonitis, bursitis, capsulitis, muscle sprain
    • generalized: fibromyalgia, polymyalgia rheumatica
• other
  ▪ neurologic: spinal stenosis/spondylolysis, degenerative disc disease, cauda equina syndrome, neoplasm, thoracic outlet syndrome, Charcot joint
  ▪ vascular: intermittent claudication

History and Physical Examination
• associated symptoms: fever, constitutional symptoms, skin lesions, conjunctivitis, urethritis
• patterns of joint involvement: polyarticular vs. monoarticular, symmetric vs. asymmetric
• inflammatory symptoms: prolonged morning stiffness, stiffness and pain ease through the day, midday fatigue, soft tissue swelling
• non-inflammatory symptoms: stiffness short lived after inactivity, short duration stiffness in the morning, pain increases with activity
• assess ROM, presence of joint effusion, warmth
• watch for: localized joint pain, erythema, warmth, swelling with pain on active ROM, inability to bear weight, fever as these may indicate presence of septic joint

Investigations
• bloodwork
  ▪ CBC, ESR, CRP, WBC, INR/PTT, blood cultures, urate
• imaging
  ▪ joint x-ray ± contralateral joint for comparison
• other investigations
  ▪ joint aspirate → send for: WBC, protein, glucose, Gram stain, crystals

Management
• septic joint: IV antibiotics ± joint decompression and drainage
• antibiotics can be started empirically if septic arthritis cannot be ruled out
• crystalline synovitis: NSAIDs at high dose, colchicine within first 24 h, corticosteroids
• do not use allopurinol, as it may worsen acute attack
• acute polyarthritis: NSAIDs, analgesics (acetaminophen ± opioids), local or systemic corticosteroids
• osteoarthritis: NSAIDs, acetaminophen
• soft tissue pain: allow healing with enforced rest ± immobilization
  ▪ nonpharmacologic treatment: local heat or cold, electrical stimulation, massage
  ▪ pharmacologic: oral analgesics, NSAIDs, muscle relaxants, corticosteroid injections, topical agents

Otalgia

Differential Diagnosis (see also Otolaryngology, OT6)
• local
  ▪ infections: acute otitis externa, acute otitis media, otitis media with effusion, mastoiditis, myringitis, malignant otitis in diabetics, herpes simplex/zoster, auricular cellulitis, external canal abscess
  ▪ others: trauma, neoplasm, foreign body, cerumen impactions, granulomatosis with polyangitis
**History**
- OPQRST
  - associated symptoms: aural fullness (feeling of pressure), otorrhea, hearing loss, tinnitus, vertigo, pruritis, fever
  - risk factors: Q-tip use, hearing aids, headphones

**Physical Exam**
- observe for otorrhea, palpation of outer ear/mastoid, otoscope to see bulging erythematous TM, perforation

**Investigations**
- consider audiogram if hearing loss
- CT head if suspicion of mastoiditis, malignant OM

**Management**
- debridement and antibiotics for cerumen and infection

---

### Seizures

- see Neurology, N14

**Definition**
- paroxysmal alteration of behaviour and/or EEG changes resulting from abnormal, excessive activity of neurons

**Categories**
- generalized seizure (consciousness always lost): tonic/clonic, absence, myoclonic, atonic
- partial seizure (focal): simple partial, complex partial
- causes: primary seizure disorder, structural (trauma, intracranial hemorrhage, infection, increased ICP), metabolic disturbance (hypo/hyperglycemia, hypo/hypernatremia, hypocalcemia, hypomagnesemia, toxins/drugs)
- differential diagnosis: syncope, pseudoseizures, migraines, movement disorder, narcolepsy/cataplexy, myoclonus

**History**
- from patient and bystander: flaccid and unconscious, often with deep rapid breathing
- preceding aura, rapid onset, loss of bladder/bowel control, tongue-biting (sides of the tongue)
- timing: length of seizure

**Physical Examination**
- injuries to head and spine and bony prominences (e.g. elbows), tongue laceration, aspiration, urinary incontinence

**Investigations**
- known seizure disorder: anticonvulsant levels
- Accu-Chek®
  - first time seizure: CBC, serum glucose, electrolytes, BUN/Cr, Ca^{2+}, Mg^{2+}; consider prolactin, β-hCG, toxicology screen
  - initial imaging: CT; x-ray if suspected extremity injuries. Definitive imaging: MRI, EEG

---

### Table 14. Management of Status Epilepticus

<table>
<thead>
<tr>
<th>Time (min)</th>
<th>Steps</th>
</tr>
</thead>
</table>
| 0-5        | Give oxygen; ensure adequate ventilation  
Monitor: vital signs, electrocardiography, oximetry  
Establish IV access; obtain blood samples for glucose level, CBC, electrolytes, toxins, and anticonvulsant levels |
| 6-9        | Give 50 mL 50% glucose (preceded by thiamine 100 mg IM in adults) |
| 10-20      | IV lorazepam 0.1 mg/kg at 2 mg/min or IV diazepam 0.2 mg/kg at 5 mg/min  
Diazepam can be repeated if seizures do not stop after 5 min; if diazepam is used to stop the status, then phenytoin should be administered promptly to prevent the recurrence of status |
| 21-60      | If status persists, administer 15-20 mg/kg of phenytoin intravenously no faster than 50 mg/min in adults and 1 mg/kg/min in children |
| >60        | If status does not stop after 20 mg/kg of phenytoin, give additional doses of 5 mg/kg to a maximal dose of 30 mg/kg  
If status persists, then give 20 mg/kg of phenobarbital IV at 100 mg/min. When phenobarbital is given after a benzodiazepine, ventilatory assistance is usually required  
If status persists, then give general anaesthesia (e.g. pentobarbital). Vaspressors or fluid volume are usually necessary. Electroencephalogram should be monitored. Neuromuscular blockade may be needed |

Adapted from: Cecil’s Essentials of Medicine, 7th edition, Table 125-7. Used with permission

---

Minimum Workup in an Adult with 1st Time Seizure
- CBC and differential  
- Electrolytes including Ca^{2+}, Mg^{2+}, P04^{3-}  
- Head CT

If administering phenytoin, patient must be on a cardiac monitor as dysrhythmias and/or hypotension may occur.
Disposition
- the decision to admit or discharge should be based on the underlying disease process identified
  - if a patient has returned to baseline function and is neurologically intact, then consider discharge with outpatient follow-up
  - first-time seizure patients being discharged should be referred to a neurologist for follow-up
  - admitted patients should generally have a neurology consult
  - patient should not drive until medically cleared (local regulations vary)
    - complete notification form to appropriate authority re: ability to drive
  - warn regarding other safety concerns (e.g. no swimming, bathing children alone, etc.)

Shortness of Breath
- see Respiratory, R3 and Cardiology, C5

Etiology
- categorized into one of two groups: respiratory or cardiovascular
  - respiratory system dyspnea: discomfort related to disorders of the central controller (brain), the ventilatory pump (ventilatory muscles, peripheral nerves), and the gas exchanger (alveoli and pulmonary capillaries)
  - cardiovascular system dyspnea: cardiac diseases (acute ischemia, heart failure, systolic dysfunction, valvular disorders, pericardial diseases, arrhythmias), anemia, and deconditioning

History/Physical
- acute SOB is often due to a relatively limited number of conditions. Associated symptoms and signs are key to the appropriate diagnosis
  - substernal chest pain with cardiac ischemia
  - fever, cough and sputum with respiratory infections
  - urticaria with anaphylaxis
  - wheezing with acute bronchospasm
  - dyspnea may be the sole complaint and the physical examination may reveal few abnormalities (e.g. pulmonary embolism, pneumothorax)
  - chest tightness may be indicative of bronchospasm
  - a sensation of rapid, shallow breathing may correspond to interstitial disease
  - a sense of heavy breathing is typical of deconditioning
  - vitals including pulse oximetry
    - wheeze (airway) vs. crackles (parenchymal), JVP, and murmurs

Investigations
- bloodwork
  - CBC and differential (hematocrit to exclude anemia), electrolytes, consider VBG
  - serial cardiac enzymes and ECG if considering cardiac source
- imaging
  - CXR (hyperinflation and bullous disease suggestive of obstructive lung disease, or changes in interstitial markings consistent with inflammation, infection or interstitial fluid)
  - CT chest usually is not indicated in the initial evaluation of patients with dyspnea, but can be valuable in patients with interstitial lung disease, occult emphysema, or chronic thromboembolic disease (PE)

Disposition
- the history and physical examination lead to accurate diagnoses in patients with dyspnea in approximately two-thirds of cases; the decision to admit or discharge should be based on the underlying disease process identified
  - consider intubation in CO₂ retainers (e.g. COPD)
  - if the decision to discharge is chosen, provide appropriate discharge instructions to return in case of returning/worsening SOB

Syncope

Definition
- sudden, transient loss of consciousness and postural tone with spontaneous recovery
- usually caused by generalized cerebral or reticular activating system hypoperfusion

Etiology
- cardiogenic: dysrhythmia, outflow obstruction (e.g. PE, tamponade, tension pneumothorax, pulmonary HTN), MI, valvular disease
- non-cardiogenic: peripheral vascular (hypovolemia), vasovagal, cerebrovascular disorders, CNS, metabolic disturbances (e.g. EtOH intoxication)
History
• gather details from witnesses, and clarify patient's experience (e.g. dizziness, ataxia, or true syncope)
• two key historical features 1. Prodrome 2. Situation
• distinguish between syncope and seizure (see Neurology, N15)
  ▪ some patients may have myoclonic jerks with syncope – NOT a seizure
  ▪ signs and symptoms during presyncope, syncope and postsyncope
  ▪ past medical history, drugs
  ▪ think anatomically in differential; pump (heart), blood, vessels, brain
• syncope is cardiogenic until proven otherwise if:
  ▪ there is sudden loss of consciousness with no warning or prodrome OR
  ▪ syncope is accompanied by chest pain

Physical Examination
• postural BP and HR
• cardiovascular, respiratory and neuro exam
• physical findings in the elderly patient who falls (I HATE FALLING):
  ▪ Inflammation of joints (or joint deformity)
  ▪ Hypotension (orthostatic blood pressure changes)
  ▪ Auditory and visual abnormalities
  ▪ Tremor (Parkinson's disease or other causes of tremor)
  ▪ Equilibrium (balance) problem
  ▪ Foot problems
  ▪ Arrhythmia (dysrhythmia), heart block or valvular disease
  ▪ Leg-length discrepancy
  ▪ Lack of conditioning (generalized weakness)
  ▪ Illness
  ▪ Nutrition (poor; weight loss)
  ▪ Gait disturbance

Investigations
• ECG (tachycardia, bradycardia, blocks, Wolff-Parkinson White, long QT interval), bedside glucose
• bloodwork: CBC, electrolytes, BUN, creatinine, ABGs, troponin, Ca²⁺, Mg²⁺, β-hCG
• consider toxicology screen

Management
• ABCs, IV, O₂, monitor
• examine for signs of trauma caused by syncopal episode
• cardiogenic syncope: admit to medicine/cardiology
• low risk syncope: discharge with follow-up as indicated by cause (non-cardiogenic syncope may still be admitted)

Disposition
• decision to admit is based on etiology
• most patients will be discharged
• on discharge, instruct patient to follow up with family physician
  ▪ educate re: avoiding orthostatic or situational syncope
  ▪ patients with recurrent syncope should avoid high-risk activities (e.g. driving)

Sexual Assault
• legally required to report sexual assault if victim is <16 yr of age to Children's Aid Society (CAS)

Epidemiology
• 1 in 4 women and 1 in 10 men will be sexually assaulted in their lifetime
• it is estimated that only 7% of rapes are reported

General Approach
• ABCs, treat acute, serious injuries
• ensure patient is not left alone and provide ongoing emotional support
• set aside adequate time for exam (usually 1.5 h)
• obtain consent for medical exam and treatment, collection of evidence, disclosure to police (notify police as soon as consent obtained)
• Sexual Assault Kit (document injuries, collect evidence) if <72 h since assault
• label samples immediately and pass directly to police
• offer community crisis resources (e.g. shelter, hotline)
• do not report unless victim requests (legally required if <16 yr old)
History

- Ensure privacy for the patient – others should be asked to leave
- Questions to ask: who? when? where did penetration occur? what happened? any weapons or physical assault?
- Post-assault activities (urination, defecation, change of clothes, shower, douche, etc.)
- Gynecologic history
  - Gravity, parity, last menstrual period
  - Contraception use
  - Last voluntary intercourse (sperm motile 6-12 h in vagina, 5 d in cervix)
- Medical history: acute injury/illness, chronic diseases, psychiatric history, medications, allergies, etc.

Physical Examination

- Evidence collection is always secondary to treatment of serious injuries
- Never re-traumatize a patient with the examination
- General examination
  - Mental status
  - Sexual maturity
  - Patient should remove clothes and place in paper bag
  - Document abrasions, bruises, lacerations, torn frenulum/broken teeth (indicates oral penetration)
- Pelvic exam and specimen collection
  - Ideally before urination or defecation
  - Examine for seminal stains, hymen, signs of trauma
  - Collect moistened swabs of dried seminal stains
  - Pubic hair combings and cuttings
  - Speculum exam
    - Lubricate with water only
    - Vaginal lacerations, foreign bodies
    - Pap smear
    - Oral/cervical/rectal culture for gonorrhea and chlamydia
    - Posterior fornix secretions if present or aspiration of saline irrigation
    - Immediate wet smear for motile sperm
    - Air-dried slides for immotile sperm, acid phosphatase, ABO group
  - Others
    - Fingernail scrapings
    - Saliva sample from victim

Investigations

- VDRL: repeat in 3 mo if negative
- Serum β-hCG
- Blood for ABO group, Rh type, baseline serology (e.g. hepatitis, HIV)

Management

- Involve local/regional sexual assault team
- Medical
  - Suture lacerations
  - Tetanus prophylaxis
  - Gynecology consult for foreign body, complex lacerations
  - Assumed positive for gonorrhea and chlamydia
    - Management: azithromycin 1 g PO x 1 dose (alt: doxycycline 100 mg PO bid x 7 d) and cefixime 800 mg PO x 1 dose
  - May start prophylaxis for hepatitis B and HIV
  - Pre and post counselling for HIV testing
  - Pregnancy prophylaxis offered
    - Levonorgestrel 0.75 mg PO STAT, repeat within 12 h (Plan B+)
  - Psychological
    - High incidence of psychological sequelae
    - Have victim change and shower after exam completed

Disposition

- Discharge if injuries/social situation permit
- Follow-up with MD in rape crisis centre within 24 h
- Best if patient does not leave ED alone

Domestic Violence

- Women are usually the victims, but male victimization also occurs
- Identify the problem (need high index of suspicion)
  - Suggestive injuries (bruises, sprains, abrasions, occasionally fractures, burns or other injuries; often do not match up with history provided)
  - Somatic symptoms (chronic and vague complaints)
  - Psychosocial symptoms
  - Clinician impression (your ‘gut feeling’, e.g. overbearing partner that won’t leave patient’s side)

Risk of Sexually Transmitted Disease After Sexual Assault

- Gonorrhea: 6-18%
- Chlamydia: 4-17%
- Syphilis: 0.5-3%
- HIV: <1%

How do you get a patient who is accompanied by her partner alone without arousing suspicion? Order an x-ray.
• if disclosed, be supportive and assess danger
• if necessary, order an x-ray to get patient alone to question
• patient must consent to follow-up investigation/reporting (unless for children)

Management
• treat injuries
• ask about sexual assault and children at home (encourage notification of police)
• document findings
• safety plan
• follow-up: family doctor/social worker

Medical Emergencies

Anaphylaxis and Allergic Reactions

Etiology
• anaphylaxis is an exaggerated immune mediated hypersensitivity reaction that leads to systemic histamine release, increased vascular permeability, and vasodilation. Regardless of the etiology, the presentation and the management of anaphylactic reactions are the same
  ▪ allergic (re-exposure to allergen)
  ▪ non-allergic (e.g. exercise induced)

Presentation
• classic presentation of anaphylaxis includes:
  1. rapid onset and progression of symptoms
  2. life threatening compromise of one or more of airway (breathing/swallowing difficulty, stridor, voice change), breathing (shortness of breath, hypoxemia, wheezing, respiratory arrest), and circulation (tachycardia, hypotension, confusion, decreased urine output, chest pain)
  3. involvement of skin (erythema, urticaria, warmness) and/or mucosa (angioedema, obstruction, GI symptoms). Not always present
• most common allergens causing anaphylaxis are food (nuts, seafood), stings, and drugs (antibiotics, anesthetics)
• the presentation of anaphylaxis is diverse and there is no one specific symptom or sign for it
  ▪ combinations of symptoms and signs will make anaphylaxis more likely
• life threatening differentials for anaphylaxis include asthma and septic shock

Management
1. immediate initial management (call for help and perform concurrently)
   ▪ give 0.5 mL of 1:1000 epinephrine IM to lateral thigh. (0.01 mL/kg up to 0.4 mL for children)
   ▪ remove causative agent if possible
   ▪ if severely compromised ABC or LOC, consult ICU immediately
   ▪ otherwise, provide 100% Oxygen through mask, give bolus 1000 mL (20 mL/kg for children)
   ▪ crystalloid IV then reassess. If IV access difficult give fluid through intraosseous route
   ▪ have continuous pulse oximetry and telemetry monitoring
   ▪ frequently monitor blood pressure
2. secondary treatment
   ▪ diphenhydramine (Benadryl®) 50 mg IM or IV q4-6h
   ▪ methylprednisolone 50-100 mg IV (dose depending on severity)
   ▪ salbutamol (Ventolin®) via nebulizer if bronchospasm

Disposition
• monitor for 4-6 h in ED (minimum) and arrange follow up with family physician in 24-48 h
• can have second phase (biphasic) reaction up to 48 h later, patient may need to be supervised (oral steroids on discharge may prevent this)
• educate patient on avoidance of allergens
• 3-day course of:
  ▪ H1 antagonist (cetirizine 10 mg PO OD or Benadryl® 50 mg PO q4-6h)
  ▪ H2 antagonist (ranitidine 150 mg PO OD)
  ▪ corticosteroid (prednisone 50 mg PO OD) generally given for 5 d

Asthma
• see Respirology, R6
• chronic inflammatory airway disease with episodes of bronchospasm and inflammation resulting in reversible airflow obstruction
Investigations
- O₂ saturation
- peak flow meter
- ± ABG if in severe respiratory distress
- CXR if diagnosis in doubt or concerns of pneumonia, pneumothorax, etc.

Table 15. Asthma Assessment and Management

<table>
<thead>
<tr>
<th>Classifications</th>
<th>History and Physical Examination</th>
<th>Management</th>
</tr>
</thead>
</table>
| Respiratory Arrest  | • Exhausted, confused, diaphoretic, cyanotic  
| Imminent            | • Silent chest, ineffective respiratory effort  
|                     | • Decreased HR, RR > 30, pCO₂ > 45 mmHg  
|                     | • O₂ sat < 90% despite supplemental O₂  
|                     | • 100% O₂, cardiac monitor, IV access  
|                     | • Intubate (consider induction with ketamine)  
|                     | • β-agonist: nebulizer 5 mg continually  
|                     | • Anticholinergics: nebulizer 0.5 mg x 3  
|                     | • IV steroids: methylprednisolone 125 mg  
| Severe Asthma       | • Agitated, diaphoretic, laboured respirations  
|                     | • Speaking in words  
|                     | • No relief from β-agonist  
|                     | • O₂ sat < 90%, FEV₁ < 50%  
|                     | • Anticipate need for intubation  
|                     | • Similar to above management  
|                     | • Magnesium sulphate 2 g IV  
|                     | • O₂ to achieve O₂-sat > 92%  
| Moderate Asthma     | • SOB at rest, cough, congestion, chest tightness  
|                     | • Speaking in phrases  
|                     | • Inadequate relief from β-agonist  
|                     | • FEV₁ 50-80%  
|                     | • β-agonist: MDI or nebs q5min  
|                     | • Steroids: prednisone 40-60 mg PO  
|                     | • Anticholinergics (Atrovent) MDI or nebs x3  
| Mild Asthma         | • Exertional SOB/cough with some nocturnal symptoms  
|                     | • Difficulty finishing sentences  
|                     | • FEV₁ > 80%  
|                     | • β-agonist  
|                     | • Monitor FEV₁  
|                     | • Consider steroids (MDI or PO)  

Disposition
- β-agonist MDI regular use (2-4 puffs q2-4h) until symptoms controlled then prn
- prednisone 30-60 mg/d for 7-14 d with no taper
- inhaled corticosteroids
- follow-up with primary care physician

Cardiac Dysrhythmias

Bradydysrhythmias and AV Conduction Blocks
- AV conduction blocks
  - 1st degree: prolonged PR interval (>200 msec), no treatment required
  - 2nd degree
    - Mobitz I: gradual prolongation of PR interval then dropped QRS complex, usually benign
    - Mobitz II: PR interval constant with dropped QRS complex, can progress to 3rd degree AV block
  - 3rd degree: P wave unrelated to QRS complex, PP and RR intervals constant
    - atropine and transcutaneous pacemaker (TCP) (atropine with caution)
    - if TCP fails consider dopamine, epinephrine IV
  - long term treatment for Mobitz II and 3rd degree block – internal pacemaker
- sinus bradycardia (rate < 60 bpm)
  - can be normal (especially in athletes)
  - can be caused by vagal stimulation, vomiting, myocardial infarction/ischemia, increased ICP, sick sinus node, hypothyroidism, drugs (e.g. β-blockers, CCBs)
  - treat if symptomatic (hypotension, chest pain)
    - acute: atropine ± transcutaneous pacing
    - sick sinus: transcutaneous pacing
    - drug induced: discontinue/reduce offending drug

Supraventricular Tachydysrhythmias (narrow QRS)
- sinus tachycardia (rate > 100 bpm)
  - causes: increased sympathetic tone, drugs, fever, hypotension, anemia, thyrotoxicosis, MI, PE, emotional, pain, etc.
  - search for and treat underlying cause, consider β-blocker if symptomatic
- regular rhythm
  - vagal maneuvers (carotid massage, Valsalva), adenosine 6 mg IV push, if no conversion give 12 mg, can repeat 12 mg dose once
  - rhythm converts: probable re-entry tachycardia (AVNRT more common than AVRT)
    - monitor for recurrence
    - treat recurrence with adenosine or longer acting medications

5 Essential Elements on History
- Cause of exacerbation
- Previous ER/ICU visits
- Previous intubations
- Timing of recent steroid use
- Frequency of asthma medication use

Treatment of Asthma
- ASTHMA
  - Adrenergics (β-agonists)
  - Steroids
  - Hydration
  - Mask (O₂)
- Antibiotics (if concurrent bacterial pneumonia)

Clinical Features of Instability
- Hypotension (sBP < 90)
- CHF or pulmonary edema
- Chest pain
- Altered LOC (may indicate shock)
Atrial Fibrillation (AFib)
- most common sustained dysrhythmia; no organized P waves (atrial rate >300/min), irregularly irregular heart rate, narrow QRS (typically)
- etiology: HTN, CAD, thyrotoxicosis, EtOH (holiday heart), valvular disease, pericarditis, cardiomyopathy, sick sinus syndrome
- treatment principles: stroke prevention, treat symptoms, identify/treat underlying cause
- decreases cardiac output by 20-30% (due to loss of organized atrial contractions)
- acute management
  - if unstable: immediate synchronized cardioversion
  - if onset of AFib is >48 h: rate control, anticoagulate 3 wk prior to and 4 wk after cardioversion or do transesophageal echo to rule out clot
  - if onset <48 h: may cardiovert
    - electrical cardioversion: synchronized direct current (DC) cardioversion
    - chemical cardioversion: procainamide, flecainide, propafenone
- long term management: rate or rhythm control, consider anticoagulation (CHADS2 score, see sidebar)

Ventricular Tachydysrhythmias (wide QRS)
- ventricular tachycardia (VT) (rate usually 140-200 bpm)
  - definition: 3 or more consecutive ventricular beats at >100 bpm
  - etiology: CAD with MI is most common cause
  - treatment: sustained VT (>30 s) is an emergency
    - hemodynamic compromise: synchronized DC cardioversion
    - no hemodynamic compromise: synchronized DC cardioversion, lidocaine, amiodarone, procainamide
- ventricular fibrillation: call a code blue, follow ACLS for pulseless arrest
- torsades de pointes
  - looks like VT but QRS 'rotates around baseline' with changing axis and amplitude (twisted ribbon)
  - etiology: prolonged QT due to drugs (e.g. quinidine, TCAs, erythromycin, quinolones), electrolyte imbalance (hypokalemia, hypomagnesemia), congenital
  - treatment:
    - IV MgSO4, temporary overdrive pacing, isoproterenol
    - correct cause of prolonged QT

Chronic Obstructive Pulmonary Disease (COPD)
- see Respirology, R8
- progressive development of irreversible airway obstruction, typically caused by smoking
- acute exacerbation: episode of increased dyspnea, coughing, increase in sputum volume or purulence

History and Physical Examination
- worsening dyspnea or tachypnea
- acute change in frequency, quantity and colour of sputum production
- triggers: pneumonia, urinary tract infection, PE, CHF, MI, drugs

Investigations
- CBC, electrolytes, ABG, CXR, ECG, PFTs

Management
- keep O2 sat 88-92% (beware of CO2 retainers, but do not withhold O2 if hypoxic)
- apply BiPAP if severe distress, arterial pH <7.35 or hypercapnic
- ipratropium is bronchodilator of choice, add salbutamol
- steroids: prednisone 40 mg PO (tapered over 3 wk)
- antibiotics: TMP-SMX, cephalosporins, respiratory quinolones (if signs of infection)
- ICU admission, if life-threatening, for ventilation (chance of ventilation dependency)
- lower threshold to admit if co-morbid illness

Disposition
- can use up to 4-6 puffs qid of ipratropium and salbutamol for exacerbations
- continue antibiotics if started and give tapering steroids
Congestive Heart Failure

• also see Cardiology, C30

Etiology
• decreased myocardial contractility: ischemia, infarction, cardiomyopathy, myocarditis
• pressure overload states: hypertension, valve abnormalities, congenital heart disease
• restricted cardiac output: myocardial infiltrative disease, cardiac tamponade
• volume overload

Causes of Exacerbation or Precipitants
• please refer to the FAILURE mnemonic on the side bar

Presentation
• left-sided heart failure
  ▪ dyspnea, decreased exercise tolerance, paroxysmal nocturnal dyspnea, orthopnea, nocturia, fatigue, possibly altered mental status, syncope, angina, systemic hypotension
  ▪ hypoxia, decreased air entry to lungs, rales, S3 or S4, pulmonary edema (on CXR), pleural effusion (usually right sided)
• right-sided heart failure
  ▪ dependent bilateral pitting edema, JVP elevation, hepatic enlargement, ascites
• patients often present with a combination of right-sided and left-sided symptoms

Investigations
• labs: CBC, electrolytes, AST, ALT, bilirubin, creatinine, BUN, cardiac enzymes, BNP (brain natriuretic peptide)
• chest x-ray (see sidebar)
• ECG: look for MI, ischemia (ST elevation/depression, T-wave inversion)
  ▪ in CHF: LVH, atrial enlargement, conduction abnormalities
• ABG: if severe or refractory to treatment
  ▪ hypoxemia, hypercapnia and acidosis are signs of severe CHF
• echocardiogram: not usually used in emergency evaluation, previous results may aid in diagnosis
• may be precipitated by dysrhythmia (e.g. sudden onset AFib) – correct if new
• rule out serious differentials such as PE, pneumothorax, pneumonia/empyema, COPD exacerbation

Management (acute)
• ABC, may require intubation if severe hypoxia
• sit upright, cardiac monitoring and continuous pulse oximetry
• saline lock IV, Foley catheter (to follow effectiveness of diuresis)
• 100% O₂ by mask
  ▪ if poor response may require BiPAP or intubation
• drugs
  ▪ nitroglycerin 0.3 mg SL q5min prn ± topical nitro patch (0.2-0.8 mg/h)
  ▪ if not responding or ischemia: 10-200 µg/min IV, titrate
  ▪ diuretic if volume overloaded (e.g. furosemide 40-80 mg IV), use caution if cause is valvulopathy
  ▪ morphine 1-2 mg IV prn
  ▪ if hypotensive: dobutamine (2.5 µg/kg/min IV) or dopamine (5-10 µg/kg/min IV), titrate up to sBP 90-100 mmHg
  ▪ ASA 160 mg chew and swallow
• treat precipitating factor (See side bars for common precipitants)
• cardiology or medicine consult

DVT and Pulmonary Embolism

• see also Respirology, R17

Risk Factors
• Virchow’s triad
  ▪ alterations in blood flow (venous stasis)
  ▪ injury to endothelium
  ▪ hypercoagulable state (including pregnancy, use of OCP, malignancy)
• clinical risk factors
Presentation

- DVT: calf pain, leg swelling/erythema/edema, palpable cord on exam; can be asymptomatic
- PE: dyspnea, pleuritic chest pain, hemoptyis, tachypnea, cyanosis, hypoxia, fever
- clinical signs/symptoms are unreliable for diagnosis and exclusion of DVT/PE; investigation often needed (see Figures 11 and 12)
- calculate the PERC (PE rule out criteria) score to assess the need for PE work-up before assessing the likelihood of a PE (Wells criteria)

Investigations (see Figures 11, 12 and 13)

- ECG and CXR are useful to look for other causes (e.g. ACS, pneumonia)
- D-dimer is only useful if it is negative in low risk patients (highly sensitive)
- ultrasound has high sensitivity and specificity for proximal clot but only 73% sensitivity for DVT below the knee (may need to repeat in 1 wk)
- CT angiography has high sensitivity and specificity for PE, may also suggest other etiology
- V/Q scan useful when CT angio not available, or patient unable to tolerate IV contrast (e.g. renal failure, allergy)

Management of DVT/PE

- LMWH unless patient also has renal failure
  - dalteparin 200 IU/kg SC q24h or enoxaparin 1.5 mg/kg SC q24h
  - warfarin started at same time as LMWH (5 mg PO OD initially)
- LMWH discontinued when INR has been therapeutic (2-3) for 2 consecutive days
  - early ambulation with analgesia is safe if appropriately anticoagulated
  - IVC filter or surgical thrombectomy considered if anticoagulation is contraindicated
  - consider thrombolyis if extensive DVT or PE causing hemodynamic compromise
  - often can be treated as outpatient, may require analgesia for chest pain (narcotic or NSAID)
  - admit if hemodynamically unstable, require supplemental O₂, major comorbidities, lack of sufficient social supports, unable to ambulate, need invasive therapy
  - consider referral to medicine for coagulopathy and malignancy work-up
  - long term anticoagulation
    - if reversible risk factor: 3-6 mo of warfarin
    - idiopathic VTE: may need longer term warfarin (5 yr or more)

Figure 11. Approach to Suspected DVT

Figure 12. Approach to suspected PE
Diabetic Emergencies

• see also Endocrinology, E11

**Diabetic Ketoacidosis (DKA)**
- severe insulin deficiency resulting in hyperglycemia (11–55 mmol/L), dehydration and electrolyte abnormalities
- history and physical examination – often young, type 1 DM, may be first presentation of undiagnosed DM (may occur in small percentage of type 2 patients)
  - early symptoms: polyuria, polydipsia, malaise, nocturia, weight loss
  - late signs and symptoms
    - anorexia, nausea, vomiting, dyspnea (often due to acidosis), fatigue
    - abdominal pain
    - drowsiness, stupor, coma
    - Kussmaul’s respiration
    - fruity acetone breath
- investigations
  - CBC, glucose, electrolytes, BUN/creatinine, Ca²⁺, Mg²⁺, phosphate, urine glucose and ketones
  - ABG
  - ECG (MI possible precipitant; electrolyte disturbances may predispose to dysrhythmia)
- management
  - rehydration
    - bolus of NS, then high rate NS infusion (beware of overhydration and cerebral edema, especially in pediatric patients)
    - beware of a pseudohypernatremia due to hyperglycemia (add 3 Na⁺ per 10 glucose over 5.5 mmol/L)
  - potassium
    - essential to avoid hypokalemia: replace KCl (20 mEq/L if adequate renal function and initial K⁺ <5.5 mmol/L)
    - use cardiac monitoring if potassium levels normal or low
  - insulin
    - critical, as this is the only way to turn off gluconeogenesis/ketosis
    - do not give insulin if K⁺ <3.3 mmol/L
    - initial bolus of 5-10 U short-acting/regular insulin (or 0.2 U/kg) IV in adults (controversial – may just start with infusion)
    - followed by continuous infusion at 5-10 U (or 0.1 U/kg) per hour
    - add D5W to IV fluids when blood glucose <15 mM to prevent hypoglycemia
    - bicarbonate is not given unless patient is at risk of death or shock (typically pH <7.0)

**Hyperosmolar Hyperglycemic State (HHS)**
- state of extreme hyperglycemia (44-133.2 mmol/L) due to relative insulin deficiency, increased counter-regulatory hormones, gluconeogenesis, and dehydration (due to osmotic diuresis) in type 2 DM, high mortality (5-20%)
- history and physical examination
  - mental disturbances, coma, delirium, seizures
  - polyuria
  - nausea, vomiting
- investigations
  - CBC, electrolytes, creatinine, BUN, glucose, Mg²⁺, phosphate, urine glucose and ketones
  - ABG
  - ECG
- management
  - rehydration with IV NS (total water deficit estimated at average 100 cc/kg body weight)
  - O₂ and cardiac monitoring, frequent electrolyte and glucose monitoring
  - insulin as required
  - identify and treat precipitant if present (the 5 Is)

**Clinical Criteria to Prevent Unnecessary Diagnostic Testing in Emergency Department Patients with Suspected Pulmonary Embolism**

*J Thromb Haemost 2004;2:1247-1255*

**Purpose:** To develop pulmonary embolism (PE) rule-out criteria (PERC) that can be used at the bedside, and prevents overtesting for PERC. Also, to prevent over-testing for PE, which includes the D-dimer test that frequently results in false positives.

**Study:** 21 variables were collected prospectively from 3148 ED patients evaluated for possible PE to develop rule-out criteria. The application of the developed rules was investigated in 1427 low-risk patients and 382 very low-risk patients.

**Results:** Eight variables were included in a block rule (age <50 yr, pulse <100 bpm, SaO₂ >94%, no unilateral leg swelling, no hemoptysis, no recent trauma or surgery, no prior PE or DVT, no hormone use) and a negative score was used to rule-out PE. In low-risk and very low-risk patients, the rule had a sensitivity of 86 and 100%, respectively and a specificity of 27 and 15%, respectively.

**Summary:** D-dimer testing for PE may not be favourable if all eight factors in the PERC are negative.
Hypoglycemia
• very common ED presentation
• management focus
  ■ treatment of hypoglycemia
  ■ investigation of cause (most often due to exogenous insulin, alcohol, sulfonylureas)
• history and physical examination
  ■ last meal, known diabetes, prior similar episodes, drug therapy and compliance
  ■ liver/renal/endocrine/neoplastic disease
  ■ depression, alcohol or drug use
• management
  ■ IV access and rapid blood glucose measurement
  ■ D50W 50 mL IV push, glucose PO if mental status permits
  • if IV access not possible, glucagon 1-2 mg IM, repeat x 1 in 10-20 min
  • O2, cardiac, frequent BG monitoring
  • thiamine 100 mg IM
  • full meal as soon as mental status permits
  • if episode due to long acting insulin, or sulfonylureas, watch for prolonged hypoglycemia due to long t1/2 (may require admission for monitoring)
  • search for cause

Electrolyte Disturbances

Table 16. Electrolyte Disturbances

<table>
<thead>
<tr>
<th>Electrolyte Disturbance</th>
<th>Common Causes</th>
<th>Symptoms</th>
<th>Treatment</th>
<th>Special Considerations</th>

<tr>
<td>Hypocalcemia</td>
<td>Iatrogenic, low Mg2+, liver dysfunction,1° hypo-PTH</td>
<td>Laryngospasm, hyperreflexia, parasthesia, tetany, Chvostek’s and Trouseau’s sign</td>
<td>Acute (ionized Ca2+ &lt;0.7 mM) requires immediate treatment: IV calcium gluconate 1-2 g in 10-20 min followed by slow infusion</td>
<td>Prolonged QT interval can arise leading to dysrhythmia as can upper airway obstruction</td>
</tr>
</tbody>
</table>

Hypertensive Emergencies

Hypertensive Emergency (Hypertensive Crisis)

Etiology
• essential hypertension, emotional exertion, pain, use of sympathomimetic drugs (cocaïne, amphetamine, etc.), MAOI use with ingestion of tyramine-containing food (cheese, red wine, etc.), pheochromocytoma, pregnancy

Presentation
• elevation of systolic and diastolic BP (irrespective of BP) with acute end-organ damage (CNS, renal, CVS, retinal)
Table 17. Signs and Symptoms of Hypertensive Emergencies

<table>
<thead>
<tr>
<th>Complication</th>

<tbody>
<tr>
<td>Stroke/TIA, headache, altered mental status, seizures, hemorrhage</td>
<td>Vision change, hemorrhage, exudates, papilledema</td>
<td>Nocturia, elevated creatinine, proteinuria, hematuria, oliguria</td>
<td>Ischemia/angina, infarct, dissection (back pain), congestive heart failure</td>
<td>Nausea, vomiting, abdominal pain, elevated liver enzymes</td>
<td></td>
</tr>
</tbody>
</table>

Investigations
- CBC, electrolytes, BUN, creatinine, urinalysis
- peripheral blood smear: to detect microangiopathic hemolytic anemia
- CXR: if SOB or chest pain
- ECG, troponins, CK: if chest pain
- CT head: if neurological findings or severe headache
- toxicology screen if sympathomimetic overdose suspected

Management
- in general, the strategy for management is to gradually and progressively reduce blood pressure in 24-48 h. Refer to Table 18 for common agents
  - lower BP by 25% over the initial 60 min by initiating antihypertensive therapy (usually nitroprusside and labetolol) or adjusting antihypertensive
  - if preeclampsia, immediately consult OB/GYN (see Obstetrics, OB16)
  - transfer to ICU for further reduction in BP under monitored setting
- in case of ischemic stroke: do not rapidly reduce blood pressure, maintain BP above 150/100 for 5 d
- in case of aortic dissection: rapid reduction of sBP to 110-120 STAT (do not resuscitate with IV fluids)
- in case of excessive catecholamines: avoid β-blockers (except labetolol)
- in case of acute coronary syndrome: address ischemia initially, then BP

Hypertensive Urgency
- definition: severely elevated blood pressure (usually sBP >180, dBP >115) with no evidence of end-organ damage
- most commonly due to non-adherence with medications
- treatment: initiate/adjust antihypertensive therapy, monitor in ED (up to 6 h) and discharge with follow up for 48-72 h
- goal: differentiate hypertensive emergencies from hypertensive urgencies

Table 18. Most Commonly Used Agents for the Treatment of Hypertensive Crisis

<td>3-5 min</td>
<td>Hypotension, bradycardia, headache, lightheadedness, dizziness</td>
<td>MI/pulmonary edema</td>
</tr>
<tr>
<td>Hydralazine</td>
<td>5-10 mg IV/IM q20min (max 20 mg)</td>
<td>5-20 min</td>
<td>2-6 h</td>
<td>Dizziness, drowsiness, headache, tachycardia, Na+ retention</td>
<td>Eclampsia</td>
</tr>
</tbody>
</table>

With CNS manifestations of severe hypertension, it is often difficult to differentiate causal relationships (i.e. hypertension could be secondary to primary cerebral event (Cushing effect)).

**Drugs that Increase Adrenergic Stimulation**
- MAOIs
- TCAs
- Amphetamines
- Cocaine

Most commonly used agents for hypertensive crisis are labetalol and nitroprusside.
Table 18. Most Commonly Used Agents for the Treatment of Hypertensive Crisis (continued)

<table>
<thead>
<tr>

*Hypotension may occur with all of these agents

Stroke

- see Neurology, N43
- can be ischemic (80% of all strokes) or hemorrhagic

Presentation
- sudden onset persisting neurological deficits

Table 19. Signs and Symptoms of Stroke

<table>
<thead>
<tr>
<th>Sign/symptoms</th>
<th>General</th>
<th>Language/throat</th>
<th>Vision</th>
<th>Coordination</th>
<th>Motor</th>

<tr>
<td>Decreased LOC, changed mental status, confusion, neglect</td>
<td>Dyssarthria, aphasia, swallowing difficulty</td>
<td>Diplopia, eye deviation, asymmetric pupils, visual field defect</td>
<td>Ataxia, intention tremor, lack of coordination</td>
<td>Increased tone, loss of power, spasticity</td>
<td>Loss of sensation</td>
<td>Hyperreflexia, clonus</td>
<td></td>
</tr>
</tbody>
</table>

Note: headache is variable

- patients with hemorrhagic stroke can present with sudden onset thunderclap headache that is usually described as “worst headache in my life”
- constellation of neurological deficits can point to certain vascular territories (Table 20)
- stroke mimics: seizure, migraine, hypoglycemia, Todds paralysis, peripheral nerve injury, Bell’s palsy, tumour, syncope

</tbody>
</table>

Investigations
- CBC, electrolytes, blood glucose, coagulation studies, ± cardiac biomarkers, ± toxicology screen
- non-contrast CT head: look for hemorrhage, ischemia
- ECG ± echocardiogram: rule out atrial fibrillation, acute MI as source of emboli
  - other imaging: carotid dopplers, CTA, MRA as appropriate

Exclusion Criteria for tPA:
- Suspected subarachnoid hemorrhage
- Previous intracranial hemorrhage
- Cerebral infarct or severe head injury within the past 3 mo
- Recent pericarditis
- Major surgery within the past 14 d
- GI or urinary hemorrhage within the past 21 d
- Recent lumbar puncture or arterial puncture at noncompressible site
- Patient is pregnant
- BP >185 mmHg systolic, or >110 mmHg diastolic
- Bleeding diathesis
- Prolonged PTT (more than 40 s) or INR >1.4
- Platelet count <100,000
- Blood glucose <2.8 or >22 mmol/L
- Intracranial hemorrhage on CT or large volume infarct
- Seizure at onset causing deficit
- Previously ADL dependent (clinical judgment)
Management

- thrombolysis: immediate assessment for eligibility. Need acute onset, <4.5 h from drug administration time AND compatible physical findings AND normal CT with no bleed
- intubation with RSI if GCS ≤8, rapidly decreasing GCS, or inadequate airway protection reflexes
- elevating head of bed if risk of elevated ICP, aspiration, or worsening cardiopulmonary status
- NPO, IV ± cardiac monitoring
  - judge fluid rate carefully to avoid overhydration (cerebral edema) as well as underhydration (underperfusion of the ischemic penumbra)
- BP control: only treat severe hypertension (sBP >200, dBP >120, mean arterial BP >140) or hypertension associated with hemorrhagic stroke transformation, cardiac ischemia, aortic dissection, or renal damage; use IV nitroprusside or labetolol
- glycemic control: keep fasting glucose less than 6.5 in acute phase (5 d)
- acute ischemic stroke: thrombolytics (rt-PA, e.g. alteplase) if within 4.5 h of symptom onset with no evidence of hemorrhage on CT scan
- antiplatelet agents: prevent recurrent stroke or stroke after TIAs, e.g. Aspirin® (1st-line); clopidogrel, Aggrenox® (2nd-line)
- anticoagulation: DVT prophylaxis if immobile; treat atrial fibrillation if present

Medications

- acute ischemic stroke: thrombolytics (rt-PA, e.g. alteplase) if within 4.5 h of symptom onset with no evidence of hemorrhage on CT scan
- antiplatelet agents: prevent recurrent stroke or stroke after TIAs, e.g. Aspirin® (1st-line); clopidogrel, Aggrenox® (2nd-line)
- anticoagulation: DVT prophylaxis if immobile; treat atrial fibrillation if present

Gynecologic/Urologic Emergencies

Vaginal Bleed

- see Gynecology, GY6 and Obstetrics, OB22

Etiology

- pregnant patient
  - 1st/2nd trimester pregnancy: ectopic pregnancy, abortion (threatened, incomplete, complete, missed, inevitable, septic), molar pregnancy, implantation bleeding, friable cervix (most common cause)
  - 2nd/3rd trimester pregnancy: placenta previa, placental abruption, premature rupture of membranes, preterm labour
  - other: trauma, bleeding cervical polyp
- postpartum
  - postpartum hemorrhage, uterine inversion, retained placental tissue, endometritis
  - non-pregnant patients
  - dysfunctional uterine bleeding, uterine fibroids, pelvic tumours, trauma, endometriosis, PID, exogenous hormones

History

- characterize bleeding (frequency, duration, number of pads/tampons, cyclicity)
- pain (if present OPQRSTU)
- menstrual history, sexual history, STI history, syncope/pre-syncope
- details of pregnancy including gush of fluid and fetal movement (>20 wk)

Physical Examination

- ABC (especially noting postural BP/HR and mucous membrane)
- abdominal examination (peritoneal signs, tenderness, distention, mass)
- speculum examination (NOT IF 2nd/3rd trimester bleeding. Perform only when placenta previa is ruled out with ultrasound)
  - look for active bleeding, trauma/anomaly, and cervical dilatation
  - use sterile speculum if pregnant
  - bimanual examination (cervical tenderness, size of uterus, cervical length/dilatation)
  - sterile gloves if pregnant

Investigations

- β-hCG test for all patients with child-bearing potential
- CBC, blood and Rh type, quantitative β-hCG, PTT, INR
- type and cross if significant blood loss
- transvaginal ultrasound (rule out ectopic pregnancy and spontaneous abortion)
- abdominal ultrasound (rule out placenta previa and fetal demise)
- postpartum
  - U/S for retained products
  - β-hCG if concerned about retained tissue

7 Causes of Emboli from the Heart

- Atrial fibrillation
- MI
- Endocarditis
- Valvular disease
- Dilated cardiomyopathy
- Left heart myxoma
- Prosthetic valves

Causes of Acute Ataxia

UNABLE TO STAND

- Underlying weakness (mimic ataxia)
- Nutritional neuropathy (vitamin B12 deficiency)
- Arteritis/vasculitis
- Basilar migraine
- Labyrinthitis/vestibular neuritis
- Encephalitis/infection
- Trauma (post-concussive)
- Other (rare genetic or metabolic disease)
- Stroke (ischemia or hemorrhage)
- Toxins (drugs, toluene, mercury)
- Alcohol
- Neoplasm/paraneoplastic syndrome
- Demyelination (Miller Fisher, Guillain Barré, MS)

Causes of Emboli from the Heart

- Atrial fibrillation
- MI
- Endocarditis
- Valvular disease
- Dilated cardiomyopathy
- Left heart myxoma
- Prosthetic valves

An ectopic pregnancy can be ruled out by confirming an intrauterine pregnancy by bedside U/S unless the patient is using NF.
Management
- ABCs
- pulse oximeter and cardiac monitors if unstable
- Rh immune globulin (Rhogam®) for vaginal bleeding in pregnancy and Rh-negative mother
- 1st/2nd trimester pregnancy
  - ectopic pregnancy: definitive treatment with surgery or methotrexate
  - intrauterine pregnancy, no concerns of coexistent ectopic: discharge patient with obstetrics follow-up
  - U/S indeterminate or β-hCG >1000-2000 IU: further work-up and/or gynecology consult
  - abortions: if complete, discharge if stable; for all others, acquire gynecology consult
- 2nd/3rd trimester pregnancy
  - placenta previa or placental abruption: obstetrics consult for possible admission
- postpartum
  - manage ABCs: start 2 large bore IV rapid infusion, type and cross 4 units of blood, consult OB/GYN immediately
- non-pregnant
  - dysfunctional uterine bleeding (prolonged or heavy flow ± breakthrough bleeding and without ovulation, a diagnosis of exclusion)
    - <35–40 yr of age: Provera® 10 mg PO OD x 10 d, warn patient of a withdrawal bleed, discharge if stable
    - if unstable, admit for IV hormonal therapy, possible D&C.
    - >35–40 yr of age: uterine sampling necessary prior to initiation of hormonal treatment to rule out endometrial cancer, U/S for any masses felt on exam
    - tranexamic acid (Cyklokapron®) to stabilize clots
  - structural abnormalities: fibroids or uterine tumours may require excision for diagnosis/treatment, U/S for workup of other pelvic masses, Pap smear/biopsy for cervical lesions

Disposition
- the decision to admit or discharge should be based on the stability of the patient, as well as the nature of the underlying cause; consult gynecology for admitted patients
- if patient can be safely discharged, ensure follow up with family physician or gynecologist
  - instruct patient to return to emergency for increased bleeding, presyncope

Nephrolithiasis (Renal Colic)
- see Urology, U16

Epidemiology and Risk Factors
- 10% of population (twice as common in males)
- recurrence 50% at 5 yr
- peak incidence 30-50 yr of age
- 75% of stones <5 mm pass spontaneously within 2 wk, larger stones may require consultation

Clinical Features
- urinary obstruction → upstream distention of ureter or collecting system → severe colicky pain
- may complain of pain at flank, groin, testes, or tip of penis
- writhing, never comfortable, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency)
- fever, chills, rigors in secondary pyelonephritis
- peritoneal findings/anterior abdominal tenderness usually absent
Differential Diagnosis of Renal Colic
- acute ureteric obstruction
- acute abdomen: biliary, bowel, pancreas, AAA
- gynecological: ectopic pregnancy, torsion/rupture of ovarian cyst
- pyelonephritis (fever, chills, pyuria, vomiting)
- radiculitis (L1): herpes zoster, nerve root compression

Investigations
- screening
  - CBC → elevated WBC in presence of fever suggests infection
  - electrolytes, Cr, BUN → to assess renal function
  - urinalysis: R&Ms (WBCs, RBCs, crystals), C&S
- imaging
  - non-contrast spiral CT is the study of choice
  - abdominal ultrasound may demonstrate stone or hydronephrosis (consider in females of child bearing age)
  - abdominal x-ray will identify large radiopaque stones (calcium, struvite, and cystine stones) but may miss smaller stones, uric acid stones or stones overlying bony structures. Consider as an initial investigation in patients who have a history of radiopaque stones and similar episodes of acute flank pain (CT necessary if film is negative)
- strain all urine → stone analysis

Management
- analgesics: NSAIDs [usually ketorolac (Toradol®) preferable over opioids], antiemetics, IV fluids
- urology consult may be indicated, especially if stone >5 mm, or if patient has signs of obstruction or infection
- α-blocker (e.g. tamsulosin) helpful to increase stone passage in select cases

Disposition
- most patients can be discharged
- ensure patient is stable, has adequate analgesia, and is able to tolerate oral medications
- may advise hydration, and limitation of protein, sodium, oxalate and alcohol intake

Ophthalmologic Emergencies
- see also Ophthalmology, OP17

History/Physical
- patient may complain of pain, tearing, itching, redness, photophobia, foreign body sensation, trauma
- mechanism of foreign body insertion – if high velocity injury suspected (welding, metal grinding, metal striking metal), must obtain orbital x-rays, ultrasound, or CT scan to exclude presence of intraocular metallic foreign body
- see Table 22 for important considerations of red eye in the emergency department
- visual acuity in both eyes, pupils, extraocular structures, fundoscopy, tonometry, slit lamp exam

Management of Ophthalmologic Foreign Body
- copious irrigation with saline for any foreign body
- remove foreign body under slit lamp exam with cotton swab or sterile needle
- antibiotic drops qid until healed
- patching may not improve healing or comfort – do not patch contact lens wearers
- limit use of topical anesthetic to examination only
- consider tetanus prophylaxis
- ophthalmology consult if globe penetration suspected

</table>

Indications for Admission to Hospital
- Intractable pain
- Fever (suggests infection) or other evidence of pyelonephritis
- Single kidney with ureteral obstruction
- Bilateral obstructing stones
- Intractable vomiting
- Compromised renal function

Always assess visual acuity in both eyes when a patient presents to the ER with an ophthalmologic complaint.

Any etiology of red eyes may also present with blurred vision.

Other Ophthalmologic Emergencies
(See also Ophthalmology, OP5)

Infectious: Red eye (Table 22), endophthalmitis, hypopyon.
Trauma: Globe rupture, orbital blow-out fractures, corneal injuries, eyelid laceration, hyphaema, lens dislocation, retrobulbar hemorrhage.
Painful vision loss: Acute iritis, corneal abrasion, globe rupture, lens dislocation, retrobulbar hemorrhage, optic neuritis, temporal arteritis, endophthalmitis, keratitis.
Painless vision loss: Central retinal vein occlusion, amaurosis fugax, occipital stroke.

Contraindications to Pupil Dilation
- Shallow anterior chamber
- Iris-supported lens implant
- Potential neurological abnormality requiring pupillary evaluation
- Caution with CV disease – mydriatics can cause tachycardia

### Dermatologic Emergencies

### Life Threatening Dermatoses

**Rash Characteristics**

**A. Diffuse Rashes**

- staphylococcal scalded skin syndrome (SSSS)
  - caused by an exotoxin from infecting strain of coagulase-positive S. aureus
  - mostly occurs in children
  - prodrome: fever, irritability, malaise and skin tenderness
  - sudden onset of diffuse erythema: skin is red, warm, and very tender
  - flaccid bullae that are difficult to see, then desquamate in large sheets
  - Nikolsky’s sign: gentle lateral stroking of skin causes epidermis to separate
- toxic epidermal necrolysis (TEN) [>30% of Body SA]
  - see also **Dermatology, D22**
  - caused by drugs (e.g. phenytoin, sulfas, penicillins and NSAIDs), bone marrow transplantation, blood product transfusions
  - usually occurs in adults
  - diffuse erythema followed by necrosis
  - severe mucous membrane blistering
  - entire epidermis desquamation
  - high mortality (>50%)
- toxic shock syndrome (TSS)
  - see also **Infectious Diseases, ID26**
  - caused by superantigen from S. aureus or GAS activating T-cell and cytokines
  - patient often presents with onset of shock and multi-organ failure, fever
  - diffuse erythematous macular rash
  - at least 3 organ systems involved: CNS, respiratory, GI, muscular, mucous membranes, renal, liver, hematologic, skin (necrotizing fasciitis, gangrene)
- vesicobullous lesions
- erythema multiforme (EM)
  - see **Dermatology, D22**
  - immunologic reaction to herpes simplex
  - viral prodrome 1-14 d before rash
  - “target lesion”: central grey bulla or wheal surrounded by concentric rings of erythema and normal skin
Stevens-Johnson syndrome (SJS) [<10% of Body SA]
- related to drugs such as antiepileptics and biologic agents, e.g. infliximab
- EM with constitutional symptoms and mucous membrane involvement (milder mucous membrane involvement than TEN)

B. Discrete Lesions
- pyoderma gangrenosum
  - often associated with immunocompromised patients (HIV, leukemia or lymphoma) with Gram-negative sepsis
  - often occurs in arms, hands, feet, or perineal region
  - usually begins as painless macule/vesicle → pustule/bulla on red/blue base → sloughing, leaving a gangrenous ulcer
- disseminated gonococcal infection (DGI)
  - see also Dermatology, D32
  - fever, skin lesions (pustules/vesicles on erythematous base ~5 mm in diameter), arthritis (joint swelling and tenderness), septic arthritis (in larger joints, e.g. knees, ankles and elbows)
  - most commonly in gonococcus positive women during menstruation or pregnancy
  - skin lesions usually appear in extremities and resolve quickly (<7 d)
- meningococcemia
  - flu-like symptoms of headache, myalgia, nausea and vomiting
  - petechial, macular or maculopapular lesions with grey vesicular centres
  - usually a few millimeters in size but may become confluent and hemorrhagic
  - usually appear in extremities but may appear anywhere
  - look for signs of meningeal irritation: Brudzinski, Kernig, nuchal rigidity, jolt accentuation

History and Physical Examination
- determine onset, course, location of skin lesions
- fever, joint pain
- associated symptoms: CNS, resp, GU, GI, renal, liver, mucous membranes
- medication history
- vitals

Investigations
- immediate consultation if patient unstable
- CBC, electrolytes, creatinine, AST, ALT, ALP, blood culture, skin biopsy, serum immunoglobulin levels (serum IgE)

Management
- general: judicious IV fluids and electrolyte control, consider vasopressors if hypotensive, prevention of infection
- determine if admission and consult needed: dermatology or infectious diseases
- specific management is determined by etiology
  - SSSS, TSS, DGI and meningococcemia
    - IV antibiotics
    - EM, SJS, and TEN
    - stop precipitating medication
    - fluids
    - symptomatic treatment: antihistamines, antacids, topical corticosteroids, systemic corticosteroids (controversial), prophylactic oral acyclovir, consider IVIG
    - TEN: debride necrotic tissue

Disposition
- most cases will require urgent care and hospitalization
- TEN: early transfer to burn centre improves outcome

Environmental Injuries

Heat Exhaustion and Heat Stroke
- predisposing factors: young persons who overexert themselves, older adults who cannot dissipate heat at rest (e.g. using anticholinergic drugs such as antihistamines or TCAs), and patients with schizophrenia who are using anticholinergic or neuroleptic medications

Heat Exhaustion (HE)
- clinical features relate to loss of circulating volume caused by exposure to heat stress
  - “water depletion”: HE occurs if lost fluid not adequately replaced
  - “salt depletion”: HE occurs when losses replaced with hypotonic fluid
Heat Stroke
• life-threatening emergency resulting from failure of normal compensatory heat-shedding mechanisms
• divided into classical and exertional subtypes (see Table 24)
• if patient does not respond relatively quickly to cooling treatments, consider other possible etiologies of hyperpyrexia (e.g. meningitis, thyroid storm, anticholinergic poisoning, delirium tremens, other infections)

<table>
<thead>
<tr>
<th>Clinical Features</th>
<th>Heat Exhaustion</th>
<th>Classical Heat Stroke</th>
<th>Exertional Heat Stroke</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Non-specific malaise, headache, fatigue</td>
<td>• Occurs in setting of high ambient temperatures (e.g. heat wave, poor ventilation)</td>
<td>• Occurs with high endogenous heat production (e.g. exercise) and overwhelmed homeostatic mechanisms</td>
<td></td>
</tr>
<tr>
<td>• Body temp &lt;40.5°C (usually normal)</td>
<td>• Often patients are older, poor, and sedentary or immobile</td>
<td>• Patients often younger, more active</td>
<td></td>
</tr>
<tr>
<td>• No coma or seizures</td>
<td>• Temp usually &gt;40.5°C</td>
<td>• Skin often diaphoretic</td>
<td></td>
</tr>
<tr>
<td>• Dehydration (T HR, orthostatic hypotension)</td>
<td>• Altered mental status, seizures, delirium, coma</td>
<td>• Other features as for classical HS, but may also have DIC, acute renal failure, rhabdomyolysis, marked lactic acidosis</td>
<td></td>
</tr>
<tr>
<td>• May have elevated AST, ALT</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Class</th>
<th>Temp</th>
<th>Symptoms/Signs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mild</td>
<td>32-34.9°C</td>
<td>Tachypnea, tachycardia, ataxia, dysarthria, shivering</td>
</tr>
<tr>
<td>Moderate</td>
<td>28-31.9°C</td>
<td>Loss of shivering, dysrhythmias, Osborne (J) waves on ECG, decreased LOC, combative behaviour, muscle rigidity, dilated pupils</td>
</tr>
<tr>
<td>Severe</td>
<td>&lt;28°C</td>
<td>Coma, hypotension, acidemia, ventricular fibrillation, asystole, flaccidity, apnea</td>
</tr>
</tbody>
</table>

R-e-warming Options
• gentle fluid and electrolyte replacement in all (due to cold diuresis)
• Passive External Re-warming (PER)
  • suitable for most stable patients with core temperature >32.2°C
  • involves covering patient with insulating blanket; body generates heat and re-warms through metabolic process, shivering
• Active External Re-warming (AER)
  • involves use of warming blankets
  • beware of “afterdrop” phenomenon
  • safer when done in conjunction with active core re-warming
• Active Core Re-warming (ACR)
  • generally for patients with core temperature <32.2°C, and/or with cardiovascular instability
  • avoids “afterdrop” seen with AER alone
  • re-warm core by using
    • warmed humidified oxygen, IV fluids
    • peritoneal dialysis with warm fluids
    • gastric/colonic/pleural irrigation with warm fluids
    • external circulation (cardiopulmonary bypass machine) is most effective, fastest
Approach to Cardiac Arrest in the Hypothermic Patient
• do all procedures gently or may precipitate VFib
• check pulse and rhythm for at least 1 min; may have profound bradycardia
• if any pulse at all (even very slow) do NOT do CPR
• if in VFib try to defibrillate up to maximum 3 shocks if core temperature <30°C
• intubate if required, ventilate with warmed, humidified O₂
• medications (vasopressors, antidysrhythmics) may not be effective at low temperatures
  ▪ controversial; may try one dose
• focus of treatment is re-warming

FROSTBITE
Classification
• ice crystals form between cells
• classified according to depth – similar to burns (1st to 3rd degree)
  • 1st degree
    ▪ symptoms: initial paresthesia, pruritus
    ▪ signs: erythema, edema, hyperemia, no blisters
  • 2nd degree
    ▪ symptoms: numbness
    ▪ signs: blistering (clear), erythema, edema
  • 3rd degree
    ▪ symptoms: pain, burning, throbbing (on thawing); may be painless if severe
    ▪ signs: hemorrhagic blisters, skin necrosis, edema, no movement

Management
• treat for hypothermia: O₂, IV fluids, maintenance of body warmth
• remove wet and constrictive clothing
• immerse in 40–42°C agitated water for 10–30 min (very painful; administer adequate analgesia)
• clean injured area, leave injured region open to air
• consider aspiration/debridement of blisters (controversial)
• debride skin
• tetanus prophylaxis
• consider penicillin G as frost bite injury at high risk of infection
• surgical intervention may be required to release restrictive eschars
• never allow a thawed area to re-chill/freeze

Burns
• see Plastic Surgery, PL16

Physical Examination
• burn size
  ▪ rule of nines (see Figure 14); does not include 1st degree burns
• burn depth
  ▪ superficial: epidermis only (e.g. sunburn)
  ▪ partial thickness: into superficial dermis deep or hair follicles, sweat glands
  ▪ full thickness: all layers of the skin
  ▪ deep: involvement of fat, muscle, even bone

Management
• remove noxious agent/stop burning process
• establish airway if needed (indicated with burns >40% BSA or smoke inhalation injury)
• resuscitation for 2nd and 3rd degree burns (after initiation of 2 large bore IVs)
• fluid boluses if unstable
  ▪ Parkland Formula: Ringer’s lactate 4 cc/kg/%BSA burned; give half in first 8 h, half in next 16 h; maintenance fluids are also required if patient cannot tolerate PO hydration
  ▪ urine output is best measure of resuscitation, should be 40–50 cc/h or 0.5 cc/kg/h; avoid diuretics
• pain relief: continuous morphine infusion with breakthrough bolus
• investigations: CBC, electrolytes, urinalysis, CXR, ECG, ABG, carboxyhemoglobin
• burn wound care: prevent infection, clean/debride with mild soap and water, sterile dressings
• escharotomy or fasciotomy for circumferential burns (chest, extremities)
• topical antibiotics, systemic antibiotics infrequently indicated
• tetanus prophylaxis if burn is deeper than superficial dermis

Disposition
• admit
  ▪ 2nd degree burns >10% BSA; any significant 3rd degree burns
  ▪ 2nd degree on face, hands, feet, perineum or across major joints
  ▪ electrical, chemical burns and inhalation injury
  ▪ burn victims with underlying medical problems or immunosuppressed patients
Inhalation Injury

Etiology
- carbon monoxide (CO), cyanide (CN) poisoning
- direct thermal injury: limited to upper airway
- smoke causes bronchospasm and edema from particulate matter and toxic inhalants (tissue asphyxiates, pulmonary irritants, systemic toxins)

History and Physical
- risk factors: closed space fires, period of unconsciousness, noxious chemicals involved
- cherry red skin (unreliable, usually post-mortem finding)
- singed nasal hairs, soot on oral/nasal membranes, sooty sputum
- hoarseness, stridor, dyspnea
- decreased LOC, confusion
- PO_{2} normal but O_{2} saturation low suggests CO poisoning

Investigations
- measure carboxyhemoglobin levels, co-oximetry
- ABG
- CXR ± bronchoscopy

Management
- CO poisoning: 100% O_{2} ± hyperbaric O_{2} (controversial)
- direct thermal injury: humidified oxygen, early intubation, pulmonary toilet, bronchodilators

Bites

MAMMALIAN BITES
- see Plastic Surgery, PL10

History
- time and circumstances of bite, symptoms, allergies, tetanus immunization status, comorbid conditions, rabies risks, HIV/hepatitis risk (human bite)
- high morbidity associated with clenched fist injuries, “fight bites”

Physical Examination
- assess type of wound: abrasion, laceration, puncture, crush injury
- assess for direct tissue damage: skin, bone, tendon, neurovascular status

Investigations
- if bony injury or infection suspected check for fracture and gas in tissue with x-rays
- get skull films in children with scalp bite wounds, ± CT to rule out cranial perforation

Initial Management
- wound cleansing and copious irrigation as soon as possible
- irrigate/debride puncture wounds if feasible, but not if sealed or very small openings; avoid hydrodissection along tissue planes
- debridement is important in crush injuries to reduce infection and optimize cosmetic and functional repair
- culture wound if signs of infection (erythema, necrosis or pus); obtain anaerobic cultures if wound foul smelling, necrotizing, or abscess; notify lab that sample is from bite wound

Prophylactic Antibiotics
- types of infections resulting from bites: cellulitis, lymphangitis, abscesses, tenosynovitis, osteomyelitis, septic arthritis, sepsis, endocarditis, meningitis
- a 3-5 d course of antibiotics is recommended for all bite wounds to the hand and should be considered in other bites if any high-risk factors present (efficacy not proven)
- dog and cat bites (pathogens: Pasteurella multocida, S. aureus, S. viridans)
  - 80% of cat bites, 5% of dog bites become infected
  - 1st line: amoxicillin + clavulanic acid
- human bites (pathogens: Eikenella corrodens, S. aureus, S. viridans, oral anaerobes)
  - 1st line: amoxicillin + clavulanic acid
- rabies (see Infectious Diseases, ID21)
  - reservoirs: warm-blooded animals except rodents, lagomorphs (e.g. rabbits)
  - post-exposure vaccine is effective; treatment depends on local prevalence
- suturing
  - vascular structures (i.e. face and scalp) are less likely to become infected, therefore consider suturing
  - allow avascular structures (i.e. pretibial regions, hands and feet) to heal by secondary intention
  - tetanus immunization if >10 yr or incomplete primary series
SNake bites
- History, physical exam, investigations and initial management similar to mammalian bites
- Additional management issues
  - Snake bites are rarely fatal but proper precautions must be taken
  - Supportive management, observe for compartment syndrome, analgesia, tetanus prophylaxis
  - Contact Provincial Poison Information Centre for consultation
  - For the Massasauga Rattle Snake ONLY: if no signs of local tissue damage and an INR is normal at 6 h after the bite, the patient may be discharged
  - There is NO evidence that constriction bands are helpful and can be harmful
  - If envenomation present, administer antivenom as directed by local Poison Information Centre

Insect bites
- Bee stings
  - 5 types of reactions to stings (local, large local, systemic, toxic, unusual)
  - History and physical exam key to diagnosis; no lab test will confirm
  - Investigations: CBC, electrolytes, BUN, creatinine, glucose, ABGs, ECG
  - ABC management, epinephrine 0.1 mg IV over 5 min if shock, antihistamines, cimetidine 300 mg IV/IM/PO, steroids, β-agonists for SOB/wheezing 3 mg in 5 mL NS via nebulizer, local site management
  - West Nile virus (see Infectious Diseases, ID27)

Near Drowning
- Most common in children <4 yr and teenagers
- Causes lung damage, hypoxemia and may lead to hypoxic encephalopathy
- Must also assess for shock, C-spine injuries, hypothermia, scuba-related injuries (barotrauma, air emboli, lung re-expansion injury)
- Complications: volume shifts, electrolyte abnormalities, hemolysis, rhabdomyolysis, renal, DIC

Physical Examination
- ABCs, vitals: watch closely for hypotension
- Lungs: rales (ARDS, pulmonary edema), decreased breath sounds (pneumothorax)
- CVS: murmurs, dysrhythmias, JVP (CHF, pneumothorax)
- H&N: assess for C-spine injuries
- Neuro: GCS or AVPU, pupils, focal deficits

Investigations
- Labs: CBC, electrolytes, ABGs, Cr, BUN, urinalysis
- Imaging: CXR (pulmonary edema, pneumothorax)
- ECG

Management
- ABCs, treat for trauma, shock, hypothermia
- Cardiac and O₂ saturation monitors, IV access
- Intensive respiratory care
  - Ventilator assistance if decreased respirations, pCO₂ >50 mmHg, or pO₂ <60 mmHg on maximum O₂
  - May require intubation for airway protection, ventilation, pulmonary toilet
  - High flow O₂/CPAP/BiPAP may be adequate but some may need mechanical ventilation with PEEP
- Dysrhythmias: usually respond to corrections of hypoxemia, hypothermia, acidosis
- Vomiting: very common, NG suction to avoid aspiration
- Convulsions: usually respond to O₂; if not, diazepam 5-10 mg IV slowly
- Bronchospasm: bronchodilators
- Bacterial pneumonia: not necessary to prophylax with antibiotics unless contaminated water or hot-tub (Pseudomonas)
- Must observe for at least 24 h as non-cardiogenic pulmonary edema may develop late

Disposition
- Non-significant submersion: discharge after short observation
- Significant submersion (even if asymptomatic): long period of observation (24 h) as pulmonary edema may appear late
- CNS symptoms or hypoxemia: admit
- Severe hypoxemia, decreased LOC: ICU
Toxicology

Alcohol Related Emergencies

- see also Psychiatry, PS22

Acute Intoxication

- slurred speech, CNS depression, disinhibition, lack of coordination
- nystagmus, diplopia, dysarthria, ataxia → may progress to coma
- hypotension (peripheral vasodilation)
- if obtunded rule out
  - head trauma/intracranial hemorrhage
  - associated depressants/street drugs, toxic alcohols
  - may also contribute to respiratory/cardiac depression
  - hypoglycemia (screen with bedside glucometer)
  - hepatic encephalopathy: confusion, altered LOC, coma
    - precipitating factors: GI bleed, infection, sedation, electrolyte abnormalities, protein meal
    - Wernicke's encephalopathy (ataxia, ophthalmoplegia, delirium)
    - post-ictal state, basilar stroke

Withdrawal

- beware of withdrawal signs (see Table 26)
- treatment:
  - diazepam 10-20 mg IV/PO or lorazepam 2-4 mg IV/PO q1hr until calm
    - frequency of dosing may have to be increased depending on clinical response
  - may use CIWA protocol and give benzodiazepines as above until CIWA <10
  - thiamine 100 mg IM/IV then 50-100 mg/d
  - magnesium sulfate 4 g IV over 1-2 h (if hypomagnesemic)
  - admit patients with delirium tremens (DT), or multiple seizures

<table>

</table>

Cardiovascular Complications

- HTN
- cardiomyopathy: SOB, edema
- dysrhythmias (“holiday heart”)
  - atrial fibrillation (most common), atrial flutter, SVT, VT (especially Torsades if hypomagnesemic/hypokalemic)

Metabolic Abnormalities

- alcoholic ketoacidosis
  - anion gap (AG) metabolic acidosis, urine ketones, low glucose and normal osmolality
  - history of chronic alcohol intake with abrupt decrease/cessation
  - malnourished, abdominal pain with nausea and vomiting
  - treatment: dextrose, thiamine (100 mg IM/IV prior to dextrose), volume repletion (with NS)
  - generally resolves in 12-24 h
- other alcohols
  - ethylene glycol → CNS, CVS, renal findings
  - methanol
    - early: lethargy, confusion
  - late: headache, visual changes, N/V, abdominal pain, tachypnea
- both produce severe metabolic acidosis with anion gap (as the alcohol is metabolized) and osmolar gap (initially after ingestion but before metabolism)

Alcohol levels correlate poorly with intoxication.

Alcohol intoxication may invalidate informed consent.

CIWA Withdrawal Symptoms

- Nausea and vomiting
- Tremor
- Paroxysmal sweats
- Anxiety
- Agitation
- Visual disturbances
- Tactile disturbances
- Auditory disturbances
- Headache
- Disorientation

10 symptoms each scored out of 7 except orientation is out of 4.

Common Deficiencies

- Thiamine
- Niacin
- Folate
- Glycogen
- Magnesium
- Potassium

Alcohol levels correlate poorly with intoxication.
• EtOH co-ingestion is protective
• treatment
  • urgent hemodialysis required
  • fomepizole 15 mg/kg IV bolus OR EtOH 10% IV bolus and infusion to achieve blood level of 22 mmol/L (EtOH loading may be done PO)
  • consider folic acid for methanol and pyridoxine and thiamine for ethylene glycol – both help reduce conversion to active metabolites
• other abnormalities associated with alcohol: hypomagnesemia, hypophosphatemia, hypocalcemia, hypoglycemia, hypokalemia

**Gastrointestinal Abnormalities**
• gastritis
  • common cause of abdominal pain and GI bleed in chronic alcohol users
• pancreatitis
  • serum amylase very unreliable in patients with chronic pancreatitis, may need serum lipase
  • hemorrhagic form (15%) associated with increased mortality
  • fluid resuscitation very important
• hepatitis
  • AST/ALT ratio >2 suggests alcohol as the cause as well as elevated GGT with acute ingestion
• peritonitis/spontaneous bacterial peritonitis
  • leukocytosis, fever, generalized abdominal pain/tenderness
  • occasionally accompanies cirrhosis
  • paracentesis for diagnosis (common pathogens: *E. coli*, *Klebsiella*, *Streptococcus*
• GI bleeds
  • most commonly gastritis or ulcers, even if patient known to have varices
  • consider Mallory-Weiss tear secondary to retching
  • often complicated by underlying coagulopathies
  • minor: treat with antacids
  • severe or recurrent: endoscopy

**Disposition**
• before patient leaves ED ensure:
  • stable vital signs, can walk unassisted, fully oriented
• offer social services to find shelter or detox program
• ensure patient can obtain any medications prescribed and can complete any necessary follow-up

---

### Approach to the Overdose Patient

#### History
• age, weight, underlying medical problems, medications
• substance and how much
• time since exposure determines prognosis and need for decontamination, symptoms since
• route
• intention, suicidality

#### Physical Examination
• focus on: ABCs, LOC/GCS, vitals, pupils

#### ABCs of Toxicology
• basic axiom of care is symptomatic and supportive treatment
• address underlying problem only once patient is stable

**A**irway (consider stabilizing the C-spine)

**B**reathing

**C**irculation

**D**rugs
  • ACLS as necessary to resuscitate the patient
  • universal antidotes

**D**raw bloods

**D**ecommodation (decrease absorption)

**E**xpose (look for specific toxidromes)/Examine the patient

**F**ull vitals, ECG monitor, Foley, x-rays

**G**ive specific antidotes and treatments

Go back and reassess

Call poison information centre

Obtain corroborative history from family, bystanders

---

### Principles of Toxicology

4 principles to consider with all ingestions:

- Resuscitation (ABCs)
- Screening (toxidrome? clinical clues?)
- Decrease absorption of drug
- Increase elimination of drug

### Suspect Overdose when:

- Altered level of consciousness/coma
- Young patient with life-threatening dysrhythmia
- Trauma patient
- Bizarre or puzzling clinical presentation
D1 – Universal Antidotes

- treatments that will not harm patients and may be essential

Dextrose (glucose)
- give to any patient presenting with altered LOC
- measure blood glucose prior to glucose administration if possible
- adults: 0.5-1.0 g/kg (1-2 mL/kg) IV of D50W
- children: 0.25 g/kg (2-4 mL/kg) IV of D25W

Oxygen
- do not deprive a hypoxic patient of oxygen no matter what the antecedent medical history (i.e. even COPD with CO2 retention)
- if depression of hypoxic drive, intubate and ventilate
- exception: paraquat or diquat (herbicides) inhalation or ingestion (oxygen radicals increase morbidity)

Naloxone (central µ-receptor competitive antagonist, shorter t½ than naltrexone)
- antidote for opioids: administration is both diagnostic and therapeutic (1 min onset of action)
- used for the undifferentiated comatose patient
- loading dose
  - adults
    - 2 mg initial bolus IV/IM/SL/SC or via ETT (ETT dose = 2-2.5x IV dose)
    - if no response after 2-3 min, increase dose by 2 mg increments until a response or to max 10 mg
    - known chronic user, suspicious history, or evidence of track marks, give 0.01 mg/kg
  - child
    - 0.01 mg/kg initial bolus IV/IO/ETT
    - 0.1 mg/kg if no response and opioid still suspected to max of 10 mg
- maintenance dose
  - may be required because half-life of naloxone (30-80 min) is much shorter than many opioids
  - hourly infusion rate at 2/3 of initial dose that produced patient arousal

Thiamine (Vitamin B1)
- 100 mg IV/IM with IV/PO glucose to all patients
- given to prevent/treat Wernicke's encephalopathy
- a necessary cofactor for glucose metabolism (may worsen Wernicke's encephalopathy if glucose given before thiamine), but do not delay glucose if thiamine unavailable
- must assume all undifferentiated comatose patients are at risk

D2 – Draw Bloods

- essential tests (see Table 28)
  - CBC, electrolytes, BUN/creatinine, glucose, INR/PTT, osmolality
  - ABGs, measure O2 sat
  - acetylsalicylic acid (ASA), acetaminophen, EtOH levels
- potentially useful tests
  - drug levels – this is NOT a serum drug screen
  - Ca2+, Mg2+, PO43–
  - protein, albumin, lactate, ketones, liver enzymes, CK – depending on drug and clinical presentation

Serum Drug Levels
- treat the patient, not the drug level
- negative toxicology screen does not rule out a toxic ingestion – signifies only that the specific drugs tested were not detectable in the specimen
- specific drugs available on general screen vary by institution; check before ordering
- urine screens also available (qualitative only)
Table 27. Toxic Gaps (see also Nephrology, NP14)

**METABOLIC ACIDOSIS**
- Increased AG: “MUDPILES CAT” (* = toxic)
- Methanol*
- Uremia
- Diabetic ketoacidosis/Starvation ketoacidosis
- Phenformin*/Paraldehyde*
- Isoniazid, Iron, Ibuprofen
- Lactate (anything that causes seizures or shock)
- Ethyleneglycol*
- Salicylates*
- Cyanide, carbon monoxide*
- Alcoholic Ketoacidosis

- Increased POG: “MAE DIE” (if it ends in “-ol”, it will likely increase the POG)
- Methanol
- Acetone
- Ethanol
- Diuretics (glycerol, mannitol, sorbitol)
- Isopropanol
- Ethylene glycol

**Decreased AG**
- Electrolyte imbalance (increased Na+/K+/Mg²⁺)
- Hypoalbuminemia (50% fall in albumin ~5.5 mmol/L decrease in the AG)
- Lithium, bromine elevation
- Paraproteins (multiple myeloma)

**Normal AG**
- High K⁺: pyelonephritis, obstructive nephropathy, renal tubular acidosis (RTA), IV, TPN
- Low K⁺: small bowel losses, acetazolamide, Renal Tubular Acidosis I, II

**Table 28. Use of the Clinical Laboratory in the Initial Diagnosis of Poisoning**

</tbody>
</table>

**D3 – Decontamination and Enhanced Elimination**

**Ocular Decontamination**
- saline irrigation to neutralize pH; alkali exposure requires ophthalmology consult

**Dermal Decontamination (wear protective gear)**
- remove clothing, brush off toxic agents, irrigate all external surfaces

**Gastrointestinal Decontamination**
- single dose activated charcoal (SDAC) (see Table 31 for drug toxidromes that are treated with charcoal)
  - adsorption of drug/toxin to AC prevents availability
  - contraindications: caustics, SBO, perforation
  - dose: 10 g/kg drug ingested or 1g/kg body weight
  - odourless, tasteless, prepared as slurry with H₂O
  - whole bowel irrigation
    - 500 mL/h (child) to 2000 mL/h (adult) of polyethylene glycol solution by mouth until clear effluent per rectum
    - start slow (500 mL in an adult) and aim to increase rate hourly as tolerated

**Substances NOT Adsorbed by Activated Charcoal**
- Lithium
- Iron
- Alcohols
- Lead
- Caustics

**Plasma Osmolar Gap (POG)**
= (2 Na⁺ + glucose + urea) – plasma osmolarity
“2 salts and a sugar BUN” – plasma osmolarity
Normal POG <10 mOsm/kg

**Anion Gap (AG)**
= Na⁺ – Cl⁻ – HCO₃⁻
Normal AG ≤12 mM/L
• indications
  • awake, alert, can be nursed upright OR intubated and airway protected
  • delayed release product
  • drug/toxin not bound to charcoal
  • drug packages (if any evidence of breakage → emergency surgery)
  • recent toxin ingestion
  • contraindications
    • evidence of ileus, perforation, or obstruction
  • surgical removal in extreme cases
    • indicated for drugs that are toxic, form concretions, or cannot be removed by conventional means
  • no evidence for the routine use of cathartics (i.e. ipecac)

Urine Alkalinization
• may be used for: ASA, methotrexate, phenobarbital, chlorpropamide
• weakly acidic substances can be trapped in alkali urine (pH >7.5) to increase elimination

Multidose Activated Charcoal (MDAC)
• may be used for: carbamazepine, phenobarbital, quinine, theophylline
• for toxins which undergo enterohepatic recirculation
• removes drug that has already been absorbed by drawing it back into GI tract
• various regimens: 12.5 g (1/4 bottle) PO q1h or 25 g (1/2 bottle) PO q2h until non-toxic

Hemodialysis
• indications/criteria for hemodialysis
  • toxins that have high water solubility, low protein binding, low molecular weight, adequate concentration gradient, small volume of distribution (Vd) or rapid plasma equilibration
  • removal of toxin will cause clinical improvement
  • advantage is shown over other modes of therapy
  • predicted that drug or metabolite will have toxic effects
  • impairment of normal routes of elimination (cardiac, renal, or hepatic)
  • clinical deterioration despite maximal medical support
• useful for the following toxins:
  • methanol
  • ethylene glycol
  • salicylates
  • lithium
  • phenobarbital
  • chloral hydrate (→ trichloroethanol)
• others include theophylline, carbamazepine, valproate, methotrexate

Position Paper Update: Ipecac Syrup for Gastrointestinal Decontamination
Clin Toxicol 2013;51:134-139
Study: Systematic review of 12 new studies (2003-2011) and summary of older studies (animal studies, volunteer studies, marker studies, case reports).
Conclusions: There is debate in the literature as to whether or not the use of ipecac should be completely abandoned, or whether it may remain useful in certain special circumstances. Concerns regarding the use of ipecac include the variability of its effects depending on elapsed time of administration and its interference with other treatments such as activated charcoal. Furthermore, ipecac has a number of side effects such as diarrhea, drowsiness and prolonged vomiting, as well as some rare side effects which may contribute to death. Despite these, ipecac has a high margin of safety. While routine administration of ipecac is not appropriate, it may be beneficial in certain circumstances. For example, its use may be considered when there is a substantial risk of serious toxicity, there are no contraindications (such as high risk of aspiration), no alternative treatment option exists or when the administration of ipecac will have no effect on the alternative treatment option and there can be timely delivery of ipecac (<90 min).

E – Expose and Examine the Patient
• vital signs (including temperature), skin (needle tracks, colour), mucous membranes, pupils, odours and CNS
• head-to-toe survey including
  • C-spine
  • signs of trauma, seizures (incontinence, “tongue biting”; etc.), infection (meningismus), chronic alcohol/drug abuse (track marks, nasal septum erosion)
• mental status

<tr>
<td></td>
<td>NaHCO₃ bolus for wide QRS/seizures</td>
<td>Intralipid therapy (consult local PIC)</td>
</tr>
</tbody>
</table>

Disposition from the Emergency Department

- methanol, ethylene glycol
  - delayed onset, admit and watch clinical and biochemical markers
- TCAs
  - prolonged/delayed cardiotoxicity warrants admission to monitored (ICU) bed
  - if asymptomatic and no clinical signs of intoxication: 6 h ED observation adequate with proper decontamination and no ECG abnormalities
  - sinus tachycardia alone (most common finding) with history of OD warrants observation in ED
- hydrocarbons/smoke inhalation
  - pneumonitis may lag 6-8 h
  - consider observation for repeated clinical and radiographic examination
- ASA, acetaminophen
  - if borderline level, get second level 2-4 h after first
  - for ASA must have at least 2 levels going down before discharge (3 levels minimum)
- oral hypoglycemics
  - admit all patients for minimum 24 h if hypoglycemic and 12 h after last octreotide dose
  - observe asymptomatic patient for at least 8 h

Psychiatric Consultation

- once patient medically cleared, arrange psychiatric intervention if required
- beware – suicidal ideation may not be expressed
Psychiatric Emergencies

Approach to Common Psychiatric Presentations

- see also Psychiatry, PS2
- before seeing patient, ensure your own safety; have security/police available if necessary

**History**

- safety
  - assess suicidality: suicidal ideation (SI), intent, plan, lethal means, past attempts
  - assess homicidality: homicidal ideation (HI), access to weapons, intended victim, history of violence
  - driving and children
  - command hallucinations
- identify current stressors and coping strategies
- mood symptoms: manic, depressive
- anxiety: panic attacks, generalized anxiety, phobias, OCD, PTSD
- psychotic symptoms: delusions, hallucinations, disorganized speech, disorganized or catatonic behaviour, negative symptoms (affective flattening, alogia, avolition)
- substance use history: most recent use, amount, previous withdrawal reactions
- past psychiatric history, medications, adherence with medications
- medical history: obtain collateral if available

**Physical**

- complete physical exam focusing on: vitals, neurological exam, signs of head trauma, signs of drug toxicity, signs of metabolic disorder
- mental status exam: general appearance, behavior, cooperation, speech, mood and affect, thought content and form, perceptual disturbances, cognition (including MMSE if indicated), judgment, insight, reliability

**Investigations**

- investigations vary with: age, established psychiatric diagnosis vs. first presentation, history and physical suggestive of organic cause
- as indicated: blood glucose, urine and serum toxicology screen, pregnancy test, electrolytes, TSH, AST/ALT, bilirubin, serum creatinine, BUN, osmolality
- blood levels of psychiatric medications
- CT head if suspect neurological etiology
- LP if indicated

**Acute Psychosis**

**Differential Diagnosis**

- primary psychotic disorder (e.g. schizophrenia)
- secondary to medical condition (e.g. delirium)
- drugs: substance intoxication or withdrawal, medications (e.g. steroids, anticholinergics)
- infectious (CNS)
- metabolic (hypoglycemic, hepatic, renal, thyroid)
- structural (hemorrhage, neoplasm)

**Management**

- violence prevention
  - remain calm, empathic and reassuring
  - ensure safety of staff and patients, have extra staff and/or security on hand
  - patients demonstrating escalating agitation or overt violent behavior may require physical restraint and/or chemical tranquilization (see Violent Patient, ER56)
- treat agitation: whenever possible, offer medication to patients as opposed to administering with force (helps calm and engage patient)
  - benzodiazepines: lorazepam 2 mg PO, IM or SL
  - antipsychotics: olanzapine 5 mg PO, haloperidol 5 mg PO/IM
- treat underlying medical condition
- psychiatry or Crisis Intervention Team consult
**Suicidal Patient**

**Epidemiology**
- attempted suicide F>M, completed suicide M>F
- second leading cause of death in people <24 yr

**Management**
- ensure patient safety: close observation, remove potentially dangerous objects from person and room
- assess thoughts (ideation), means, action (preparatory, practice attempts), previous attempts
- admit if there is evidence of intent and organized plan, access to lethal means, psychiatric disorder, intoxication (suicidal ideation may resolve with few days of abstinence)
- patient may require certification if unwilling to stay voluntarily
- do not start long-term medications in the emergency department
- psychiatry or crisis team consult

**Violent Patient**

**Differential Diagnosis**
- rule out lethal organic cause (e.g. EtOH, drugs, and head injuries)

**Prevention**
- be aware and look for prodromal signs of violence: anxiety, restlessness, defensiveness, verbal attacks
- try to de-escalate the situation: address the patient’s anger, empathize

**Restraints**
- pharmacological
  - often necessary – may mask clinical findings and impair exam
  - haloperidol 5-10 mg IM (be prepared for dystonic reactions, especially with multiple doses of neuroleptics over a short period) + lorazepam 2 mg IM/IV
  - look for signs of anticholinergic overdose first (see Table 29)
  - benzodiazepines best option if suspected substance-induced violence
- physical
  - present option to patient in firm but non-hostile manner
  - sufficient people to carry it out safely
  - restrain supine or on side; preferably 4-point restraints, never less than 2-points (opposite arm and leg)
  - suction and airway support available in case of vomiting
  - once restrained, search person/clothing for drugs and weapons

Respiratory Distress

- see also Pediatrics, P92

History and Physical Examination
- infants not able to feed, older children not able to speak in full sentences
- anxious, irritable, lethargic – may indicate hypoxia
- tachypnea >60 (>40 if preschool age, >30 if school age), retractions, tracheal tug
  - see Pediatrics Table 1, P3 for age specific vital signs
- pulsus paradoxus
- wheezing, grunting, vomiting

¹Now rare with Hib vaccine in common use

Management
- croup (usually laryngotracheitis caused by parainfluenza viruses)
  - humidified O₂ should not be given (no evidence for efficacy)
  - racemic epinephrine q1h x 3 doses, observe for ‘rebound effects’ nebulized 1:1000 epi (racemic has limited availability)
  - dexamethasone x 1 dose
  - consider bacterial tracheitis/epiglottitis if unresponsive to croup therapy
- bacterial tracheitis
  - start croup therapy, but may have poor response
  - usually require intubation, ENT consult, ICU
  - start antibiotics (e.g. cloxacillin), pending C&S
- epiglottitis
  - 4 Ds: drooling, dyspnea, dysphagia, dysphonia + tripod sitting
  - do not examine oropharynx or agitate patient
  - immediate anesthesia, ENT call – intubate
  - then IV fluids, antibiotics, blood cultures
- asthma
  - supplemental O₂ if saturation <90% or PaO₂ <60%
  - bronchodilator therapy: salbutamol (Ventolin®) 0.15 mg/kg by masks q20min x 3
  - add 250-500 µg ipratropium (Atrovent®) to first 3 doses salbutamol
  - give corticosteroid therapy as soon as possible after arrival (prednisolone 2 mg/kg, dexamethasone 0.3 mg/kg)
  - if critically ill, not responding to inhaled bronchodilators or steroids: give IV bolus, then infusion of MgSO₄
  - IV β₂-agonists if critically ill and not responding to above

Admission Criteria for Croup
- Stridor at rest or significant respiratory distress
- Relapse after 2 doses of epinephrine or incomplete response
- Co-morbid respiratory or underlying condition

Admission Criteria for Asthma
- Respiratory distress 6 h after steroids
- Ventolin required >q3h
- Need for supplemental oxygen
- Consider if previous ICU admission
- Significant fatigue or lethargy
Febrile Infant and Febrile Seizures

**FEBRILE INFANT**
- see also Pediatrics, P54
- for fever >38°C without obvious focus
  - <28 d
    - admit
    - full septic work up (CBC and differential, blood C&S, urine C&S, LP ± stool C&S, CXR if indicated)
    - treat empirically with broad spectrum IV antibiotics
  - 28-90 d
    - as above unless infant meets Rochester criteria (see sidebar), investigate as indicated by history and physical
  - >90 d
    - toxic: admit, treat, full septic workup
    - non-toxic and no focus: investigate as indicated by history and physical

**FEBRILE SEIZURES**
- see also Pediatrics, P87

**Etiology**
- children aged 6 mo to 6 yr with fever or history of recent fever
- simple vs. complex febrile seizures
- normal neurological exam afterward
- no evidence of intracranial infection or history of previous non-febrile seizures
- often positive family history of febrile seizures
- relatively well looking after seizure

**Investigations and Management**
- if it is a febrile seizure: treat fever and look for source of fever
- if not a febrile seizure: treat seizure and look for source of seizure
- ± EEG (especially if first seizure), head U/S (if fontanelle open)

Table 34. Simple vs. Complex Febrile Seizures

**Child Abuse and Neglect**

- see also *Pediatrics*, P14
- obligation to report any suspected/known case of child abuse or neglect to CAS yourself (do not delegate)
- document injuries
- consider skeletal survey x-rays (especially in non-ambulatory child), ophthalmology consult, CT head
- injury patterns associated with child abuse
  - head injuries: torn frenulum, dental injuries, bilateral black eyes, traumatic hair loss, diffuse severe CNS injury, retinal hemorrhage
  - Shaken Baby Syndrome: diffuse brain injury, subdural/subarachnoid hemorrhage, retinal hemorrhage, minimal/no evidence of external trauma, associated bony fractures
  - skin injuries: bites, bruises/burns in shape of an object, glove/stocking distribution of burns, bruises of various ages, bruises in protected areas
  - bone injuries: rib fractures without major trauma, femur fractures age <1 yr of age, spiral fractures of long bones in non-ambulatory children, metaphyseal fractures in infants, multiple fractures of various ages, complex/multiple skull fractures
  - genitourinary/gastrointestinal injuries: chronic abdominal/perineal pain, injury to genitals/rectum, STI/pregnancy, recurrent vomiting or diarrhea

**Presentation of Neglect**

- Failure to thrive, developmental delay
- Inadequate or dirty clothing, poor hygiene
- Child exhibits poor attachment to parents
**Procedural Sedation**

- Procedural sedation: the technique of sedative or dissociative agent administration with or without analgesics to induce a state that allows a patient to tolerate an unpleasant or painful procedure while maintaining all protective cardiorespiratory functions (i.e. a depressed level of consciousness without loss of a patient’s protective airway reflexes).
  - must weigh degree of pain and expected relief versus risk/complications of sedation and procedure

**Requirements for Safe Procedural Sedation in the Emergency Department**

- Airway suitable for safe intubation and ventilation
- Appropriate equipment/personnel available
- Intact and functioning cardiorespiratory and neurological system
- Ideally, NPO for minimum 4-6 h
- Anesthetic history and drug allergies, including manifestations
- Appropriate IV access, monitoring (oxygen saturation, BP, HR, etc.)
- Informed consent obtained

**Common Procedural Sedation Medications (titrate to effect)**

- See Common Medications, below

**Common Medications**

**GENERAL FUNCTION OF ORGANS**

The Hypothalamic-Pituitary Axis

Information about cortical inputs, automatic function, environmental cues (light, temp) and peripheral hormonal feedback is synthesized at the coordinating center of the endocrine system, the hypothalamus. The hypothalamus then sends signals to the pituitary to release hormones that affect the thyroid, adrenals, gonads, growth, milk production and water balance.

**Anatomy**

- **Function**
  - Hypothalamic hormones: small peptides, non-binding protein → rapid degradation
  - High [ ] in pituitary-portal blood system
  - Low [ ] in peripheral circulation
  - Proximity of axis preserves the pulsatile output signals from the hypothalamic neurons.

**Thyroid**

- Thyroid hormone is critical to 1) brain and somatic development in fetus and infants, 2) metabolic activity in adults, and 3) function of virtually every organ system.

**Adrenal**

- Each gland, 6-8 g, has 1) a cortex with 3 layers that act like independent organs ( zona glomerulosa → aldosterone, fasciculata → cortisol, reticularis → androgen and estrogen precursors), and 2) a medulla that acts like a sympathetic ganglion to store/synthesize adrenaline and noradrenaline.

**Gonads**

- Bilfunctional: sex steroid synthesis and gamete production.

**Overview of Lipid Transport**

- Lipoproteins are spherical complexes that consist of a lipid core surrounded by a shell of water-soluble cholesterol, apoproteins and phospholipids.
- Lipoproteins transport lipids within the body.
- Apolipoproteins serve as enzyme co-factors, promote clearance of the particle by interacting with cellular receptors and stabilize the lipoprotein micelle.

**Dyslipidemias**

Definition
- Metabolic disorders characterized by elevations of fasting plasma LDL-cholesterol, and/or triglycerides (TG), and/or low HDL-cholesterol.

SECONDARY HYPERTRIGLYCERIDEMIA

Etiology
• endocrine: obesity/metabolic syndrome, hypothyroidism (more for high LDL, not TG), acromegaly, Cushing’s syndrome, diabetes mellitus
• renal: chronic renal failure, polyclonal and monoclonal hypergammaglobulinemia
• hepatic: chronic liver disease, hepatitis, glycogen storage disease
• drugs: alcohol, corticosteroids, estrogen, hydrochlorothiazide, retinoic acid, β-blockers without intrinsic sympathomimetic action (ISA), anti-retroviral drugs, atypical antipsychotics, oral contraceptive pills
• other: pregnancy

Dyslipidemia and the Risk for CAD

• increased LDL is a major risk factor for atherosclerosis and CAD as LDL is the major atherogenic lipid particle
• increased HDL is associated with decreased cardiovascular disease and mortality
• moderate hypertriglyceridemia (triglyceride level 2.3-9 mmol/L) is an independent risk factor for CAD, especially in people with diabetes mellitus and in post-menopausal women
• treatment of hypertriglyceridemia has not been shown to reduce CAD risk
Screening
- screen men over age 40, women over age 50 or post-menopausal
- if following risk factors present, screen at any age:
  - diabetes
  - cigarette smoking
  - hypertension (sBP >140, dBP >90)
  - obesity
  - family history of premature coronary artery disease
  - clinical signs of hyperlipidemia (xanthelasma, xanthoma, arcus cornealis)
  - evidence of atherosclerosis
  - rheumatoid arthritis, SLE, psoriasis
  - HIV infection on highly active antiretroviral therapy (HAART)
  - chronic kidney disease (estimated GFR <60 mL/min/1.73 m²)
  - erectile dysfunction
- screen children with a family history of hypercholesterolemia or chylomicronemia

Factors Affecting Risk Assessment
- metabolic syndrome
- apolipoprotein B (apo B):
  - each atherogenic particle (VLDL, LDL, LDL and lipoprotein A) contains one molecule of apo B
  - serum [apo B] reflects the total number of particles and may be useful in assessing cardiovascular risk and adequacy of treatment in high risk patients and those with metabolic syndrome
- C-reactive protein (hs-CRP) levels:
  - highly sensitive acute phase reactant
  - may be clinically useful in identifying those at a higher risk of cardiovascular disease than predicted by the global risk assessment

Treatment of Dyslipidemias

Approach to Treatment
For clinical guidelines see Can J Cardiol 2012;29:151-167
- estimate 10-yr risk of CAD using Framingham model
- establish treatment targets according to level of risk (see Table 5)

Table 6. Treatment of Hypercholesterolemia and Hypertriglyceridemia

### Treatment of Hypercholesterolemia
- **Conservative:** 4-6 mo trial unless high risk group, in which case medical treatment should start immediately
  - **Diet:**
    - Decrease fat: <30% calories
    - Decrease saturated fat: <10% calories
    - Decrease cholesterol: <200 mg/d
    - Increase fibre: >30 g/d
    - Decrease alcohol intake to ≤1-2 drinks/d
    - Smoking cessation
    - Aerobic exercise: ≥150 min/wk in bouts of ≥10 min
    - Weight loss: target body mass index (BMI) <25
  - **Medical**
    - HMG-CoA reductase inhibitors, ezetimibe, bile acid sequestrants, niacin (see Common Medications, E52)

- **Intensive Lipid Lowering in CAD: TNT**
  - **Study:** Multicentre, randomized, double-blinded trial with median follow-up of 4.9 yr
  - **Patients:** 10,001 patients with CAD and LDL-C <3.4 mmol/L
  - **Intervention:** 80 mg versus 10 mg atorvastatin daily.
  - **Main outcomes:** Death from CAD, MI, cardiac arrest, or stroke.
  - **Results:** A primary event occurred in 8.7% of the patients receiving intensive therapy, compared to 10.0% of patients receiving standard therapy (RR 0.8, p<0.001). There was no change in overall mortality. Incidence of persistent transaminase elevations was higher in the intensive therapy group (1.2% versus 0.3%, p<0.001).
  - **Conclusion:** Intensive statin therapy is associated with lower rates of CAD events than standard therapy, but also a higher rate of transaminase elevation.

- **Intensive Lipid Lowering in CAD: TNT**
  - **Study:** Randomized, double-blind, placebo-controlled trial (median follow-up 5.0 yr).
  - **Patients:** 20,536 patients with coronary disease, other occlusive arterial disease or diabetes (aged 40-80 yr) who had a total cholesterol level of ≥3.5 mmol/L.
  - **Intervention:** Simvastatin 40 mg/d or placebo.
  - **Main outcomes:** Mortality, fatal or non-fatal vascular events.
  - **Results:** The use of simvastatin significantly decreased total mortality (12.9 vs. 14.7, p=0.0003) and the first event rate of any cardiovascular event by 25% (p<0.001).
  - **Conclusion:** Treatment with simvastatin improved survival and cardiovascular outcomes in high-risk CAD patients.

### Treatment of Hypertriglyceridemia
- **Conservative:** 4-6 mo trial
  - **Diet:**
    - Decrease fat and simple carbohydrates
    - Increase omega-3 polyunsaturated fatty acid
    - Control blood sugars
    - Decrease alcohol intake to ≤1-2 drinks/d
    - Smoking cessation
    - Aerobic exercise: ≥150 min/wk in bouts of ≥10 min
    - Weight loss: target body mass index (BMI) <25
  - **Medical:** fibrates, niacin (see Common Medications, E52)
    - **Indications:**
      - Failed conservative measures
      - TG > 10 mmol/L (885 mg/dL) to prevent pancreatitis
      - Combined hyperlipidemia

Table 5. Target Lipids by Risk Group

</tbody>
</table>
**Overview of Glucose Regulation**

**Pre-Diabetes (Impaired Glucose Tolerance/Impaired Fasting Glucose)**
- 1-5% per yr go on to develop diabetes mellitus
- 50-80% revert to normal glucose tolerance
- weight loss may improve glucose tolerance
- increased risk of developing macrovascular complications
- lifestyle modifications decrease progression to DM by 58%

**Diagnostic Criteria**
- impaired fasting glucose (IFG): fasting blood glucose (FBG) 6.1-6.9 mmol/L (110-125 mg/dL)
- impaired glucose tolerance (IGT): 2h 75 g oral glucose tolerance test (OGTT) 7.8-11.0 mmol/L (140-200 mg/dL)

**Diabetes Mellitus (DM)**

**Definition**
- syndrome of disordered metabolism and inappropriate hyperglycemia secondary to an absolute/relative deficiency of insulin, or a reduction in biological effectiveness of insulin, or both

**Diagnostic Criteria**
- any one of the following is diagnostic:
  - presence of classic symptoms of DM (polyuria, polydipsia, polyphagia, weight loss, blurry vision, nocturia, ketonuria) PLUS random blood glucose (BG) ≥11.1 mmol/L (200 mg/dL)
  - on at least two separate occasions:
    - FPG ≥7.0 mmol/L (126 mg/dL) (fasting = no caloric intake for at least 8 h) OR
    - 2h 75 g OGTT ≥11.1 mmol/L (200 mg/dL) OR
    - random PG ≥11.1 mmol/L (200 mg/dL) OR
    - HbA1c ≥6.5%

*In the absence of symptomatic hyperglycemia, if a single laboratory test result is in the diabetes range, a repeat confirmatory laboratory test (FPG, A1c, 2hPG in a 75 g OGTT) must be done on another day.*
Etiology and Pathophysiology

Table 7. Etiologic Classification of Diabetes Mellitus

<table>
<thead>
<tr>
<th>Category</th>
<th>Type 1 Diabetes</th>
<th>Type 2 Diabetes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Onset</td>
<td>• Usually &lt;30 yr of age</td>
<td>• Usually &gt;40 yr of age</td>
</tr>
<tr>
<td>Epidemiology</td>
<td>• More common in Caucasians</td>
<td>• More common in Blacks, Hispanics, Aboriginals, and Blacks</td>
</tr>
<tr>
<td>Genetics</td>
<td>• Monozygotic twin concordance is 30-40%</td>
<td>• Greater heritability than Type 1 DM</td>
</tr>
<tr>
<td>Pathophysiology</td>
<td>• Synergistic effects of genetic, immune, and environmental factors that cause β-cell destruction resulting in impaired insulin secretion</td>
<td>• Impaired insulin secretion, peripheral insulin resistance (likely due to receptor and post receptor abnormality), and excess hepatic glucose production</td>
</tr>
<tr>
<td>Natural history</td>
<td>• After initial presentation, honeymoon period often occurs where glycemic control can be achieved with little or no insulin treatment as residual cells are still able to produce insulin</td>
<td>• Early on, glucose tolerance remains normal despite insulin resistance as β cells compensate with increased insulin production</td>
</tr>
<tr>
<td>Circulating autoantibodies</td>
<td>• Islet cell Ab present in up to 60-85%</td>
<td>• &lt;10%</td>
</tr>
</tbody>
</table>

Table 8. Comparison of Type 1 and Type 2 Diabetes Mellitus

<table>
<thead>
<tr>
<th>Onset</th>
<th>Type 1</th>
<th>Type 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usually &lt;30 yr of age</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Increasing incidence in pediatric population 2nd to obesity</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Usually &gt;40 yr of age</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Infections:
- Autoimmune
- Monogenic insulin resistance
- Genetic susceptibility
- Complex and multifactorial

Drug-induced:
- β-cell death
- GAD (glutamic acid decarboxylase)
- Islet cell Ab present in up to 60-85%
- 80% of β cells lost before features of diabetes present

Synergistic effects of genetic, immune, and environmental factors that cause β-cell destruction resulting in impaired insulin secretion.

Autoimmune process is believed to be triggered by environmental factors (e.g., viruses, bovine milk protein, urea compounds).

Beta cells are infiltrated with lymphocytes resulting in islet cell destruction.

80% of β cells mass destroyed before features of diabetes present.

Intensive blood glucose control in Type 2 DM – UKPDS 33

Lancet 1998;352:837-853

Randomized controlled trial (mean follow-up 10 yr).

Patients: 3867 patients with newly diagnosed Type 2 DM (mean age 53 yr, 67% men, 87% white, mean fasting plasma glucose (FPG) 6.1-10.0 mmol/L). Exclusions included severe cardiovascular disease, renal disease, retinopathy, and others.

Intervention: Intensive treatment with a sulfonylurea or insulin (target FPG <6 mmol/L) vs. conventional treatment with diet alone (target FPG <7.5 mmol/L) without hyperglycemic symptoms).

Main outcomes: Diabetes-related endpoints (MI, angina, heart failure, stroke, renal failure, amputation, retinopathy, blindness, death from hyperglycemia or hypoglycemia), diabetes-related death, and all-cause mortality.

Results: Patients allocated to intensive treatment had lower median HbA1c levels (p<0.001).

Outcome | RRR % (p value) |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Diabetes-related endpoint</td>
<td>12 (0.029)</td>
</tr>
<tr>
<td>Diabetes-related death</td>
<td>10 (0.34)</td>
</tr>
<tr>
<td>All-cause mortality</td>
<td>6 (0.44)</td>
</tr>
</tbody>
</table>

Patients allocated to intensive therapy had more hypoglycemic episodes and greater weight gain.

Conclusion: Intensive blood glucose control reduces microvascular, but not macrovascular complications in Type 2 DM.

**Treatment of Diabetes**

**Glycemic Targets**
- HbA1c reflects glycemic control over 3 mo and is a measure of patient’s long-term diabetes control
- therapy in most individuals with type 1 or type 2 diabetes should be targeted to achieve a HbA1c ≤7.0% in order to reduce the risk of microvascular and if implemented early in the course of disease, macrovascular complications
- more intensive glucose control, HbA1c <6.5%, may be targeted in patients with a shorter duration of diabetes with no evidence of significant CVD and longer life expectancy, to further reduce risk of nephropathy and retinopathy; provided this does not result in a significant increase in hypoglycemia
- a HbA1c target <8.5% may be more appropriate in type 1 and type 2 patients with limited life expectancy, higher level of functional dependency, a history of recurrent severe hypoglycemia, multiple co-morbidities, extensive CAD, and a failure to attain established glucose targets despite treatment intensification
- there may be harm associated with strategy to target HbA1c <6.0% in certain patients with Type 2 DM (see ACCORD trial, E9)

**Diet**
- daily carbohydrate intake 45-60% of energy, protein 15-20% of energy and fat <35% of energy
- intake of saturated fats <7% and polyunsaturated fats <10% of total calories each
- limit sodium, alcohol and caffeine intake
- Type 1: carbohydrate counting is used to titrate insulin regimen
- Type 2: weight reduction

**Lifestyle**
- regular physical exercise to improve insulin sensitivity, lower lipid concentrations and control blood pressure
- smoking cessation

**Medical Treatment: Oral Antihyperglycemic Agents and/or Incretin Therapy (Type 2 DM)**
- initiate oral antihyperglycemic therapy and/or incretin therapy within 2-3 mo if lifestyle management does not result in glycemic control
- if HbA1c >9.0%, initiate pharmacologic therapy immediately and consider combination oral therapy or insulin immediately
- see Common Medications, E52 for details on antihyperglycemic agents

**Medical Treatment: Insulin (Figure 5)**
- used for Type 1 DM at onset, may be used in Type 2 DM at any point in treatment
- routes of administration: subcutaneous injections, continuous subcutaneous insulin infusion pump, IV infusion (regular insulin only)
- bolus insulins: short-acting (Insulin regular), rapid-acting analogue (Insulin aspart, Insulin lispro, Insulin glulisine)
- basal insulins: intermediate-acting (Insulin NPH), long-acting analogue (Insulin detemir, Insulin glargine)
- premixed insulins (% Humulin R and % NPH) 30/70; premixed insulin analogues (Biphasic Insulin aspart, Insulin lispro/lispro protamine)
- estimated total daily insulin requirement: 0.5-0.7 units/kg (often start with 0.3-0.5 units/kg/day)

Timely adjustments to and/or addition of antihyperglycemic agents should be made to attain target Hba1c within 6 to 12 months

Effects of Intensive Glucose Lowering in Type 2 DM: The ACCORD Trial
NEJM 2010;362:1563-1574

Study: Multicentre RCT.
Population: 10,251 patients (mean age 62.2) with Type 2 DM, and cardiovascular risk factors.

Intervention: Intensive therapy targeting a Hba1c level of <6.0% or standard therapy targeting 7.0 to 7.6%.

Outcomes: First occurrence of nonfatal MI, nonfatal stroke, or death from CV causes.

Results: The intensive therapy arm was stopped early (3.5 yr vs. 5.6 yr planned) due to evidence of increased mortality. There was no difference in primary outcome for either study arm. There was a significant increase in all-cause mortality, CV-cause mortality, nonfatal MI, and all congestive heart failure in the intensive therapy group. There were increased rates of all hypoglycemic events, any hypoglycemic serious adverse events, fluid retention, and weight gain >10 kg, but lower systolic and diastolic blood pressure in the intensive treatment group. There was an increased incidence of elevated ALT (>3 times upper limit) and ACE drug use in the standard therapy group.

Conclusions: Intensive glucose lowering therapy in Type 2 DM does not improve clinical outcomes and actually increases the risk of mortality with more adverse events compared to standard therapy. Additional research is required to discern the cause.

Effects of Intensive Blood Pressure Control in Type 2 DM: The ACCORD Trial
NEJM 2010;362:1575-1585

Study: RCT, unblinded with 4.7 yr of mean follow-up.

Population: 7,733 patients with type 2 DM, risk factors for cardiovascular (CV) disease, systolic blood pressure (sBP) between 130-180 mmHg.

Intervention: sBP control less than 120 mmHg (intensive) or 140 mmHg (standard).

Primary Outcomes: Major CV event (composite nonfatal MI, nonfatal stroke, or CV-related death).

Results: Mean number of medications at 1 yr for intensive therapy was 3.4 (95% CI, 3.4-3.5) versus 2.1 (95%, 2.1-2.2) for standard therapy. There was a significant increase in all serious adverse events in the intensive treatment arm (3.3% vs. 1.2%, p < 0.001), especially bradycardia or arrhythmia (0.3% vs. 0.1%, p = 0.03) and hyperkalemia (0.4% vs. 0.0%, p < 0.01). There was no significant difference in primary outcomes in the two study arms, or all-cause mortality. There was a significant reduction in any stroke (0.32% vs. 0.57% p = 0.01) and nonfatal stroke incidences (0.30% vs. 0.47% p = 0.03) in the intensive therapy arm.

Conclusions: Intensive BP lowering to less than 120 mmHg versus 140 mmHg in patients with Type 2 DM and CV risk factors does not reduce major CV event risk reduction except for stroke events.

Effects of Combination Lipid Therapy in Type 2 DM: The ACCORD Trial
NEJM 2010;362:1583-1594

Study: RCT, double-blinded trial with 4.7 yr of mean follow-up.

Population: 5,518 patients with type 2 DM.

Intervention: Statin therapy in patients with Type 2 DM does not improve clinic outcomes and actually increases the risk of mortality with more adverse events compared to standard therapy. Additional research is required to discern the cause.
**Insulin Regimens**

**Table 10. Insulin Regimens for T2DM and T1DM**

<table>
<thead>
<tr>
<th>Regimen</th>
<th>Administration</th>
</tr>
</thead>
</table>
| T2DM Oral hypoglycemic agent + basal insulin | • Start with 10 units at bedtime of basal insulin  
• Titrate up by 1 unit until FBG <7.0 mmol/L (126 mg/dL) |
| T1DM Multiple daily injections (MDI) | • Estimated total insulin requirement is 0.5-0.7 U/kg  
• 40% is given as basal insulin at bedtime  
• 20% is given as bolus insulin before breakfast, lunch and dinner  
• Continue metformin but discontinue secretagogue |
| Split-mixed           | • Estimated total insulin requirement is 0.5-0.7 U/kg  
• 2/3 dose is given as pre-mixed insulin before breakfast  
• 1/3 dose is given as pre-mixed insulin before dinner  
• Continue metformin but discontinue secretagogue |

*Bolus insulin: Aspart, Glulisine, Lispro  
*Basal insulin: Gargine, Detemir, NPH  
*Pre-mixed insulin: Humulin 30/70, Novolin 30/70, Novomix 30, Humalog Mix25, Humalog Mix50

</tbody>
</table>

**Variable Insulin Dose Schedule (“Sliding/Supplemental/Correction Scale”)**
- for patients on Basal-Bolus MDI regimen: patient takes usual doses of basal insulin but varies doses of bolus insulin based on BG reading at time of dose
- use baseline bolus insulin dose when within BG target range; add or subtract units when above or below target
- when used in hospital (including perioperative management of diabetes) patient should also receive basal insulin to prevent fluctuations in blood sugar levels or long periods of hyperglycemia without intervention
- construction of a supplemental sliding scale for a patient on anti-hyperglycemics:
  - Correction Factor (CF) = 100/Total Daily Dose of insulin (TDD)
  - BG <4: call MD and give 15 g carbohydrates
  - BG between 4 to 8: no additional insulin
  - BG between 8 to (8 + CF): give one additional unit
  - BG between (8 + CF) to (8 + 2CF): give two additional units
  - BG between (8 + 2CF) to (8 + 3CF): give three additional units

**Insulin Pump Therapy [continuous subcutaneous insulin infusion (CSII)]**
- external battery-operated device provides continuous basal dose of rapid-acting insulin analogue (aspart, glulisine or lispro) through small subcutaneous catheter
- at meals, patient programs pump to deliver insulin bolus
- provides improved quality of life and flexibility
- risk of DKA if pump is inadvertently disconnected

Conversion chart adapted from Nathan DM et al.  
The clinical information value of a glycosylated hemoglobin assay. AJEM 1986;310:341-346

**DPP-IV Inhibitors**
- Newer antihyperglycemic agents (e.g. sitagliptin, saxagliptin) that inhibit the degradation of endogenous incretin hormones like GLP-1
- Stimulate insulin secretion, inhibit glucagon release from the pancreas

**GLP-1 Analogues (Incretins)**
- Human glucagon-like peptide-1 analogues: exenatide, liraglutide
- Increase insulin secretion, decreases inappropriate glucagon secretion, increases B-cell growth/replation, slows gastric emptying and decreases food intake
- Associated with weight loss
- Subcutaneous formulation

**Treatment of DKA/HHS**
- Fluids
- Insulin
- Potassium
- Search for and treat precipitant

**The 8 Is Precipitating DKA:**
- Infection
- Ischemia or Infarction
- Intravenous (glucocorticoids)
- Intoxication
- Insulin missed
- Initial presentation
- Intra-abdominal process (e.g. pancreatitis, cholecystitis)
- Intrasp/periop stress
### Acute Complications

#### Table 12. Acute Complications of Diabetes Mellitus: Hyperglycemic Comatose States

<table>
<thead>
<tr>
<th></th>
<th>Diabetic Ketoacidosis (DKA)</th>
<th>Hyperosmolar Hyperglycemic State (HHS)</th>
</tr>
</thead>
</table>

#### Pathophysiology
- Usually occurs in Type 1 DM
- Insulin deficiency with counterregulatory hormones (glucagon, cortisol, catecholamines, GH)
- Can occur with lack of insulin (non-adherence, inadequate dosage, 1st presentation) or increased stress (surgery, infection, exercise)
- Unrestricted hepatic glucose production → hyperglycemia → osmotic diuresis → dehydration and electrolyte disturbance → ↓ Na⁺ (veter shift to ECF)
- Fat mobilization → ↑ FFA → ketoacids → metabolic acidosis
- Severe hyperglycemia exceeds the renal threshold for glucose and ketone reabsorption → glucosuria and ketonuria
- Total body K⁺ depletion but serum K⁺ may be normal or elevated
- 2° to shift from ICF to ECF due to lack of insulin, ↑ plasma osmolality
- Total body PO₄³⁻ depletion

#### Clinical Features
- Polyuria, polydipsia, polyphagia with marked fatigue, nausea, vomiting
- Dehydration (orthostatic changes)
- LDC may be ↓ with ketoacidosis or with high serum osmolality
- Abdominal pain
- Fruity smelling breath
- Kussmaul’s respiration

#### Serum
- ↑ BG (typically 11.5-55 mmol/L, 198-990 mg/dL), ↓ Na⁺ (2° to hyperglycemia → for every ↑ in BG by 10 mmol/L (180 mg/dL) there is a ↓ in Na⁺ by 3 mmol/L)
- Normal or ↑ K⁺, ↓ HCO₃⁻; ↑ BUN, ↑ Cr, ketonemia, ↓ PO₄³⁻
- ↑ osmolality

#### ABG
- Metabolic acidosis with ↑ AG, possible 2° respiratory alkalosis
- If severe vomiting/dehydration there may be a metabolic alkalosis
- Metabolic acidosis absent unless underlying precipitant leads to acidosis (e.g. lactic acidosis in MI)
- History of ingesting large amounts of glucose containing fluids
- History of decreased fluid intake
- History of ingesting large amounts of glucose containing fluids
- Dehydration (orthostatic changes)
- ↓ LDC → lathyrophy, confusion, coma due to high serum osmolality
- Kussmaul’s respiration is absent unless the underlying precipitant has also caused a metabolic acidosis

#### Urine
- + ve for glucose and ketones
- – ve for ketones unless there is starvation ketosis
- Glycosuria

#### Treatment
- Immediate resuscitation and emergency measures if patient is stuporous or comatose
- Monitor degree of ketoacidosis with AG, not BG or serum ketone level
- Rehydration:
  - 1 L/ h NS in first 2 h
  - after 1st 2 L, 300-400 mL/h 0.45% NaCl (continue NS if corrected sodium is falling faster than 3 mosm/kg water/h)
  - once BG reaches 13.9 mmol/L (250 mg/dL) then switch to D5W to maintain BG in the range of 13.9–16.6 mmol/L (250-300 mg/dL)
- Insulin therapy:
  - critical to resolve acidosis, not hyperglycemia
  - do not use with hypokalemia (see below), until serum K⁺ is corrected to >3.3 mmol/L
  - use only regular insulin (R)
  - maintain on 0.1 U/kg/h insulin R infusion
  - check serum glucose hourly
- K⁺ replacement:
  - with insulin administration, hypokalemia may develop
  - if serum K⁺ <3.3 mmol/L, hold insulin and give 40 mEq/L K⁺ replacement
  - when K⁺ 3.5-5.0 mmol/L add KC1 20-40 mEq/L IV fluid to keep K⁺ in the range of 3.5-5.5 mEq/L
- HCO₃⁻;
  - if pH < 7.0 or if hypotension, arrhythmia or coma is present with a pH of <7.1 give HCO₃⁻ in 0.45% NaCl
  - do not give if pH >7.1 (risk of metabolic alkalosis)
  - can give in case of life-threatening hyperkalemia

#### Prognosis
- 2-5% mortality in developed countries
- Serious morbidity from sepsis, hypokalemia, respiratory complications, thromboembolic complications, and cerebral edema
- Overall mortality approaches 50% primarily because of the older patient population and underlying etiology/precipitant
Macrovacular Complications

- increased risk of coronary artery disease (CAD), ischemic stroke, and peripheral arterial disease secondary to accelerated atherosclerosis
- coronary artery disease (see Cardiology, C22)
  - risk of MI is 3-5x higher in those with diabetes compared to age-matched controls
  - CAD is the leading cause of death in Type 2 DM
  - most patients with DM are considered "high risk" under the risk stratification for CAD (see Dyslipidemias, E2)
- ischemic stroke (see Neurology, N43)
  - risk of stroke is approximately 2.5x higher in those with diabetes
  - level of glycemia is both a risk factor for stroke and a predictor of a poorer outcome in patients who suffer a stroke
  - HbA1c level is a significant and independent predictor of the risk of stroke
- peripheral arterial disease (see Cardiology, C44)
  - manifested by intermittent claudication in lower extremities, intestinal angina, foot ulceration
  - risk of foot gangrene is 30x higher in those with diabetes compared to age-matched controls
  - risk of lower extremity amputation is 15x higher in those with diabetes
- treatment
  - tight blood pressure control (<130/80 mmHg); especially for stroke prevention
  - tight glycemic control in early DM without established CVD (refer to ACCORD, VADT, ADVANCE, DCCT, EDIC, UKPDS extension studies)
  - tight low density lipoprotein (LDL) cholesterol control [LDL <2.0 mmol/L (77 mg/dL)]
  - ACE inhibitor or angiotensin receptor blocker in high-risk patients
  - smoking cessation

Microvascular Complications

DIABETIC RETINOPATHY (see Ophthalmology, OP35)

Epidemiology
- Type 1 DM: 25% affected at 5 yr, 100% at 20 yr
- Type 2 DM: 25% affected at diagnosis, 60% at 20 yr
- leading cause of blindness in North America between the ages of 20-74
- most important factor is disease duration

Clinical Features
- nonproliferative
  - asymptomatic but if macular involvement occurs vision may be impaired
  - microaneurysms, hard exudates, dot-blot and flame hemorrhages
- preproliferative
  - macular edema, cotton wool spots, venous shunts and beading, intra-retinal microvascular abnormalities (IRMA)
- proliferative
  - with neovascularization and fibrous scarring; great risk for loss of vision secondary to vitreous hemorrhage (floaters) and/or retinal detachment

Treatment and Prevention
- tight glycemic control (delays onset, decreases progression), tight lipid control, manage hypertension, smoking cessation
- pan-retinal laser photocoagulation for treatment of neovascularization
- vitrectomy
- annual follow-up visits with an optometrist or ophthalmologist examination through dilated pupils whether symptomatic or not (immediate referral after diagnosis of Type 2 DM; 5 yr after diagnosis of Type 1 DM)
- interval for follow-up should be tailored to severity of retinopathy

Laboratory Testing: Ketones

The nitroprusside test for ketones identifies acetone and acetoacetate but does NOT detect β-hydroxybutyrate (BHB), the ketone most frequently in excess. This has two clinical consequences:
- Be wary of a patient with a clinical picture of DKA but negative serum or urinary ketones. These could be false negatives because of the presence of BHB.
- As DKA is treated, BHB is converted to acetone and acetoacetate. Serum or urinary ketones may therefore rise, falsely suggesting that the patient is worsening when in fact they are improving.

Laboratory Testing: Microalbuminuria

The primary end point was the time to death from any cause. Other endpoints examined were death from CV causes and various CV events along with diabietic neuropathy, nephropathy, and retinopathy.

Results:
- Twenty-four patients in the intensive-therapy group died, as compared with 40 in the conventional-therapy group (hazard ratio, 0.54; 95% confidence interval [CI], 0.32 to 0.88; p=0.02).
- Intensive therapy was associated with a lower risk of death from CV causes (hazard ratio, 0.43; 95% CI, 0.19 to 0.94; p=0.04) and of CV events (hazard ratio, 0.41; 95% CI, 0.25 to 0.67; p<0.001).
- One patient in the intensive-therapy group had progression to end-stage renal disease, as compared with six patients in the conventional-therapy group (p=0.04). Fewer patients in the intensive-therapy group required revascularization (relative risk, 0.45; 95% CI, 0.23 to 0.86; p=0.02).

Conclusions:
- In-risk patients with Type 2 DM, intensive intervention with multiple drug combinations and behaviour modification had sustained beneficial effects with respect to vascular complications and on rates of death from any cause and from CV causes.
DIABETIC NEPHROPATHY (see Nephrology, NP28)

Epidemiology
• diabetes-induced renal failure is the most common cause of renal failure in North America
• 20-40% of persons with Type 1 DM (after 5-10 yr) and 4-20% with Type 2 DM have progressive nephropathy

Pathophysiology
• thickening of capillary basement membrane and glomerular mesangium resulting in glomerulosclerosis and renal insufficiency
• diffuse glomerulosclerosis is more common than nodular intercapillary glomerulosclerosis (Kimmelstiel-Wilson lesions)

Screening
• serum creatinine
• random urine test for albumin to creatinine ratio (ACR) plus urine dipstick test for all Type 2 DM patients at diagnosis, then annually, and for postpubertal Type 1 DM patients with ≥5 yr duration of DM

Clinical Features
• initial changes include microalbuminuria, increased GFR (up to 140%) from hyperfiltration, enlarged kidneys
• microalbuminuria: ACR of >2.0 mg/mmol (men) or >2.8 mg/mmol (women)
• macroalbuminuria: ACR of >20.0 mg/mmol (men) or >28.0 mg/mmol (women)
• progression over 15 yr to cause hypertension, persistent proteinuria (macroalbuminuria), nephrotic syndrome, and renal failure
• elevated HbA1c is an independent risk factor for progression to microalbuminuria

Treatment and Prevention
• tight glycemic control
• tight blood pressure control (<130/80 mmHg); can use either ACEI or ARB (often used first line for their CVD protection)
• even in the absence of glycemic control ACEIs or ARBs reduce the level of albuminuria and the rate of progression of renal disease in normotensive and hypertensive patients with Type 1 or Type 2 DM
• Type 1 DM → CKD with either hypertension or albuminuria → ACEIs 1st line; ARBs 2nd line
• Type 2 DM → CKD with hypertension and albuminuria → ACEIs or ARBs (dose adjust if creatinine clearance (CrCl) <60 mL/min)
• consider use of non-dihydropyridine calcium channel blocker (e.g. diltiazem) in those unable to tolerate both ACEIs and ARBs
• limit use of nephrotoxic drugs and dyes
• renal failure may necessitate hemodialysis and renal transplant

DIABETIC NEUROPATHY (see Neurology, N37)

Epidemiology
• approximately 50% of patients within 10 yr of onset of Type 1 DM and Type 2 DM

Pathophysiology
• can have peripheral sensory neuropathy, motor neuropathy or autonomic neuropathy
• mechanism poorly understood
• acute cranial nerve palsies and diabetic amyotrophy are thought to be due to ischemic infarction of peripheral nerve
• the more common motor and sensory neuropathies are thought to be related to metabolic or osmotic toxicity secondary to increased sorbitol and/or decreased myoinositol (possible mechanisms include accumulation of advanced glycation endproducts [AGE], oxidative stress, protein kinase C, nerve growth factor deficiency)

Screening
• 128 Hz tuning fork or 10 g monofilament at diagnosis and annually in people with Type 2 DM and after 5 yr duration of Type 1 DM
### Clinical Features

#### Table 13. Clinical Presentation of Diabetic Neuropathies

<table>
<thead>
<tr>
<th>Peripheral Sensory Neuropathy</th>
<th>Motor Neuropathy</th>
<th>Autonomic Neuropathy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paresthesias (tingling, itching), neuropathic pain, radicular pain, numbness, decreased tactile sensation</td>
<td>Less common than sensory neuropathy</td>
<td>Postural hypotension, tachycardia, decreased cardiovascular response to Valsalva maneuver</td>
</tr>
<tr>
<td>Bilateral and symmetric with decreased perception of vibration and pain/temperature; especially true in the lower extremities but may also be present in the hands</td>
<td>Delayed motor nerve conduction and muscle weakness/atrophy</td>
<td>Gastroparesis and alternating diarrhea and constipation</td>
</tr>
<tr>
<td>Decreased ankle reflex</td>
<td>May involve one nerve trunk (mononeuropathy) or more (mononeuropathy multiplex)</td>
<td>Urinary retention and erectile dysfunction</td>
</tr>
<tr>
<td>Symptoms may first occur in entrapment syndromes e.g. carpal tunnel</td>
<td>Some of the motor neuropathies spontaneously resolve after 6-8 wk</td>
<td></td>
</tr>
<tr>
<td>May result in neuropathic ulceration of foot</td>
<td>Reversible CN palsies: III (ptosis/ophthalmoplegia, pupil sparing), VI (inability to laterally deviate eye), and VII (Bell’s palsy)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Diabetic amyotrophy: refers to pain, weakness, and wasting of hip flexors or extensors</td>
<td></td>
</tr>
</tbody>
</table>

#### Treatment and Management

- tight glycemic control
- for neuropathic pain syndromes: tricyclic antidepressants (e.g. amitriptyline), pregabalin, duloxetine, anti-epileptics (e.g. carbamazepine, gabapentin), and capsaicin
- foot care education
- Jobst® fitted stocking and tilting of head of bed may decrease symptoms of orthostatic hypotension
- treat gastroparesis with domperidone and/or metoclopramide (dopamine antagonists), erythromycin (stimulates motilin receptors)
- medical, mechanical and surgical treatment for erectile dysfunction (see Urology, U30)

### Other Complications

#### Dermatologic
- diabetic dermopathy: atrophic brown spots commonly in pretibial region known as “skin spots”, secondary to increased glycosylation of tissue proteins or vasculopathy
- eruptive xanthomas secondary to increased triglycerides
- necrobiosis lipoidica diabeticorum: rare complication characterized by thinning skin over the shins allowing visualization of subcutaneous vessels

#### Bone and Joint Disease
- juvenile cheiroarthropathy: chronic stiffness of hand caused by contracture of skin over joints secondary to glycosylated collagen and other connective tissue proteins
- Dupuytren’s contracture
- bone demineralization: bone density 10-20% below normal
- frozen shoulder

#### Cataracts
- subcapsular and senile cataracts secondary to glycosylated lens protein or increased sorbitol causing osmotic change and fibrosis

#### Infections
- see Infectious Diseases, ID16

### Hypoglycemia

#### Etiology and Pathophysiology
- hypoglycemia occurs most frequently in people with diabetes receiving insulin or certain antihyperglycemic therapies (insulin secretagogues)
- in people without diabetes, care must be taken to distinguish fasting from post-prandial hypoglycemia as each invokes separate differential diagnoses
Table 14. Common Causes of Hypoglycemia

Clinical Features
- Whipple's triad
  1. serum glucose <2.5 mmol/L (45 mg/dL) in males and <2.2 mmol/L (40 mg/dL) in females
  2. neuroglycopenic symptoms
  3. rapid relief provided by administration of glucose
- adrenergic symptoms (typically occur first; caused by autonomic nervous system activity)
  - palpitations, sweating, anxiety, tremor, tachycardia
- neuroglycopenic symptoms (caused by decreased activity of CNS)
  - dizziness, headache, clouding of vision, mental dullness, fatigue, confusion, seizures, coma

Investigations
- electrolytes, creatinine, LFTs, drugs/toxins, cortisol
- if concerned about possible insulinoma:
  - bloodwork to be drawn when patient is hypoglycemic (e.g. during hospitalized 72-h fast) for glucose, serum ketones, insulin, pro-insulin, C-peptide, insulin antibodies

Treatment
- for fasting hypoglycemia, must treat underlying cause
- for post-prandial (reactive) hypoglycemia, frequent small feeds
- see Emergency Medicine, ER36
- treatment of hypoglycemic episode in the unconscious patient or patient NPO
  - D50W 50 mL (1 ampule) IV or 1 mg glucagon SC (if no IV available)
  - may need ongoing glucose infusion once BG >5 mmol/L (90 mg/dL)

Metabolic Syndrome
- several definitions, most widely used are National Cholesterol Education Program (NCEP/ATP III, updated by American Heart Association) and International Diabetes Federation (IDF) definitions (see sidebar)
- postulated syndrome related to insulin resistance associated with hyperglycemia, hyperinsulinemia, hypertension, central obesity, and dyslipidemia
- obesity aggravates extent of insulin resistance
- complications include diabetes, atherosclerosis, CAD, MI, and stroke
- women with PCOS are at increased risk for developing insulin resistance, hyperlipidemia, and metabolic syndrome
- not to be confused with syndrome X related to angina pectoris with normal coronary arteries (Prinzmetal angina)

Obesity
- see Family Medicine, FM7

Use C-peptide Levels to Distinguish between Exogenous and Endogenous Source of Hyperinsulinemia
- Increased = endogenous
- Decreased or normal = exogenous

Treatment of Acute Hypoglycemic Episode (Blood Glucose <4.0 mmol/L) in the Awake Patient (e.g. able to self-treat)
1) Eat 15 g of carbohydrates (CHO) (e.g. 3 packets sugar dissolved in water; 3/4 cup of juice)
2) Wait 15 min
3) Retest Blood Glucose (BG)
4) Repeat steps 1-3 until BG >5 mmol/L
5) Eat next scheduled meal. If next meal is >1 h away, eat snack including 15 g of CHO and protein.

Hypoglycemia Unawareness: (Type 1 DM >> > > Type 2 DM)
- Patient remains asymptomatic until severely hypoglycemic levels are reached
- Causes:
  - Decreased glucagon/epinephrine response
  - History of repeated hypoglycemia or low HbA1c
  - Autonomic neuropathy
  - Not safe to drive

Suggest that patient obtain a Medic-Alert bracelet if at risk for hypoglycemia, especially with hypoglycemia unawareness.

WC = Waist circumference
Pituitary Gland

Pituitary Hormones

Figure 6. Hypothalamic-pituitary hormonal axes

**Hypothalamic Control of Pituitary**
- trophic and inhibitory factors control the release of pituitary hormones
- most hormones are primarily under trophic stimulation except prolactin which is primarily under inhibitory control by dopamine, as well as GH and TSH which are inhibited by SS (somatostatin)
- transection of the pituitary stalk (i.e. dissociation of hypothalamus and pituitary) leads to pituitary hypersecretion of prolactin and hyposecretion of all remaining hormones

**Anterior Pituitary Hormones**
- growth hormone (GH), luteinizing hormone (LH), follicle stimulating hormone (FSH), thyroid stimulating hormone (TSH), adrenocorticotropic hormone (ACTH), and prolactin (PRL)

**Posterior Pituitary (Hypothalamic) Hormones**
- antidiuretic hormone (ADH) and oxytocin
- peptides synthesized in the supraoptic and paraventricular nuclei of the hypothalamus
- although ADH and oxytocin are produced in the hypothalamus these hormones are stored and released from the posterior pituitary

**Growth Hormone (GH)**

**GH DEFICIENCY**
- cause of short stature in children (see Pediatrics, P27)
- controversial significance in adults; often not clinically apparent, may present as fatigue

**GH EXCESS**
- in children (before epiphyseal fusion) leads to gigantism
- in adults (after epiphyseal fusion) leads to acromegaly

**Etiology**
- GH secreting pituitary adenoma, carcinoid or pancreatic islet tumours secreting ectopic GHRH resulting in excess GH

**Pathophysiology**
- normally GH is a catabolic hormone that acts to increase blood glucose levels
- in growth hormone excess states secretion remains pulsatile but there is loss of hypoglycemic stimulation, glucose suppression, and the nocturnal surge
- proliferation of bone, cartilage, soft tissues, organomegaly
- insulin resistance and IGT

**Clinical Features**
- enlargement of hands and feet, coarsening of facial features, thickening of calvarium, prognathism, thickening of skin, increased sebum production, sweating, acne, sebaceous cysts, fibromata mollusca, acanthosis nigricans, arthralgia, carpal tunnel syndrome, degenerative osteoarthritis, thyromegaly, renal calculi, hypertension, cardiomyopathy, obstructive sleep apnea, colonic polyps and DM
Investigations
- glucose suppression test is the most specific test (75 g of glucose PO suppresses GH levels in healthy individuals but not in patients with acromegaly)
- elevated serum insulin-like growth factor-1 (IGF-1) is usually first line diagnostic test

Treatment
- surgery, octreotide (somatostatin analogue), dopamine agonist (bromocriptine/cabergoline), growth hormone receptor antagonist (pegvisomant), radiation

**Prolactin (PRL)**

**HYPERPROLACTINEMIA**

**Etiology**
- pregnancy and breastfeeding
- prolactinoma: most common pituitary adenoma (prolactin-secreting tumours may be induced by estrogens and grow during pregnancy)
- pituitary masses with pituitary stalk compression causing reduced dopamine inhibition of prolactin release
- primary hypothyroidism (increased TRH)
- decreased clearance due to chronic renal failure or severe liver disease (prolactin is metabolized by both the kidney and liver)
- medications with anti-dopaminergic properties are a common cause of high prolactin levels: antipsychotics (common), antidepressants, antihypertensives, anti-migraine agents (triptans/ergotamines), bowel motility agents (metoclopramide/domperidone), H₂-blockers (ranitidine)
- macroprolactinemia (high molecular weight prolactin also known as big big prolactin)

**Clinical Features**
- galactorrhea (secretion of breast milk in women and, rarely, men), infertility, hypogonadism, amenorrhea, erectile dysfunction

**Investigations**
- serum PRL, TSH, liver enzyme tests, creatinine
- MRI

**Treatment**
- long-acting dopamine agonist: bromocriptine, cabergoline or quinagolide (Norprolac™)
- surgery ± radiation (rare)
- prolactin-secreting tumours are very slow-growing and sometimes require no treatment
- if medication-induced, consider stopping medication if possible
- in certain cases if microprolactinoma and not planning on becoming pregnant, may consider OCP

**Thyroid Stimulating Hormone (TSH)**
- see Thyroid, E20

**Adrenocorticotropic Hormone (ACTH)**
- see Adrenal Cortex, E29

**Luteinizing Hormone (LH) and Follicle Stimulating Hormone (FSH)**
- see Gynecology, GY4

**HYPOGONADOTROPIC HYPOGONADISM**

**Clinical Features**
- hypogonadism, amenorrhea, erectile dysfunction (see Urology, U30), loss of body hair, fine skin, testicular atrophy, failure of pubertal development

**Treatment**
- Pergonal™ (combined FSH/LH hormone therapy), hCG, or pulsatile GnRH analogue if fertility desired
- symptomatic treatment with estrogen/testosterone

Approach to Nipple Discharge
- Differentiate between galactorrhea (fat droplets present) versus breast discharge (usually unilateral, may be bloody or serous)
- If galactorrhea, determine if physiologic (e.g. pregnancy, lactation, stress) versus pathologic
- If abnormal breast discharge, must rule out a breast malignancy
HYPERGONADOTROPIC HYPOGONADISM
• 2° hypersecretion in gonadal failure (e.g. in menopause)

**Antidiuretic Hormone (ADH)**

**DIABETES INSIPIDUS (DI)**

**Definition**
• disorder resulting from deficient ADH action causing passage of large volumes of dilute urine

**Etiology and Pathophysiology**
• central DI: insufficient ADH due to pituitary surgery, tumours, idiopathic/autoimmune, stalk lesion, hydrocephalus, histiocytosis X, trauma, familial central DI
• nephrogenic DI: collecting tubules in kidneys resistant to ADH due to drugs (e.g. lithium), hypercalcemia, hypokalemia, chronic renal disease, hereditary nephrogenic DI
• psychogenic polydipsia and osmotic diuresis must be ruled out

**Clinical Features**
• passage of large volumes of dilute urine, polydipsia, dehydration; hypernatremia can develop with lack of access to water or impaired thirst mechanism

**Diagnostic Criteria**
• fluid deprivation will differentiate true DI (high urine output persists, urine osmolality < plasma osmolality) from psychogenic DI (psychogenic polydipsia)
• response to exogenous ADH (DDAVP) will distinguish central from nephrogenic DI

**Treatment**
• DDAVP/vasopressin for central DI
• chlorpropamide, clofibrate, thiazides, NSAIDs or carbamazepine as second line or for partial DI
• nephrogenic DI treated with solute restriction NSAIDs and thiazide diuretics; DDAVP (if partial)

**SYNDROME OF INAPPROPRIATE ADH SECRETION (SIADH)**

**Diagnostic Criteria**
• hyponatremia with corresponding plasma hypo-osmolality, urine sodium concentration above 40 mEq/L, urine less than maximally diluted (>100 mOsm/kg), euvoolemia (edema absent), and absence of adrenal, renal or thyroid insufficiency

**Etiology and Pathophysiology**
• stress (pain, nausea, post-surgical)
• malignancy (lung, pancreas, lymphoma)
• CNS disease (inflammatory, hemorrhage, tumour, Guillain-Barré syndrome)
• respiratory disease (TB, pneumonia, empyema)
• drugs (SSRIs, vincristine, chlorpropamide, cyclophosphamide, carbamazepine, nicotine, morphine, DDAVP, oxytocin)

**Treatment**
• treat underlying cause, fluid restriction (800-1000 mL/day), vasopressin receptor antagonists (e.g. tolvaptan, conivaptan), and demeclocycline (antibiotic with anti-ADH properties, rarely-used) fluidocortisone, furosemide

**Pituitary Pathology**

**PITUITARY ADENOMA** (see Neurosurgery, NS14)

**Clinical Features**
• local mass effects
  - visual field defects (bitemporal hemianopia due to compression of the optic chiasm), diplopia (due to oculomotor nerve palsies), headaches; increased ICP is rare
• hypofunction
• hypopituitarism (see sidebar)
• hyperfunction
  - PRL (galactorrhea), GH (acromegaly in adults, gigantism in children), ACTH (Cushing’s disease = Cushing’s syndrome caused by a pituitary tumour)
  - tumours secreting LH, FSH and TSH are rare

**Presentations of Pituitary Lesions:**
• Mass effect (visual field deficits, diplopia, ptosis, headaches, CSF leak)
• Hyperfunction
• Hypofunction

**Important Deficiencies to Recognize**
• Adrenal insufficiency
• Hypothyroidism

Concurrent adrenal insufficiency and hypothyroidism should be treated with glucocorticoids first and then with thyroid hormone to avoid adrenal crisis.
Investigations
- radiological evaluation (MRI is imaging procedure of choice)
- formal visual field testing
- hypothalamic-pituitary hormonal function

HYPOPITUITARISM

Etiology (the eight Is)
- Invasive
  - pituitary tumours, craniopharyngioma, cysts (Rathke’s cleft, arachnoid or dermoid), metastases
- Infarction/hemorrhage
  - Sheehan’s syndrome (pituitary infarction due to excessive post-partum blood loss and hypovolemic shock)
  - pituitary apoplexy (acute hemorrhage/infarction of a pituitary tumour; presents with sudden loss of pituitary hormones, severe headache and altered level of consciousness; can be fatal if not recognized and treated early)
- Infiltrative/inflammatory
  - sarcoidosis, hemochromatosis, histiocytosis
- Infectious
  - syphilis, TB, fungal (histoplasmosis), parasitic (toxoplasmosis)
- Injury
  - severe head trauma
- Immunologic
  - autoimmune destruction
- Iatrogenic
  - following surgery or radiation
- Idiopathic
  - familial forms, congenital midline defects

Investigations
- triple bolus test
  - stimulates release of all anterior pituitary hormones in normal individuals
  - rapid sequence of IV infusion of insulin, GnRH and TRH
  - insulin (usual dose 0.1 unit/kg of human regular insulin) → hypoglycemia → increased GH and ACTH
  - GnRH (100 µg IV push) → increased LH and FSH
  - TRH (200 µg IV push over 60 s) → increased TSH and PRL (no longer available)

Thyroid

Thyroid Hormones

Figure 7. Thyroid hormone synthesis
Synthetic Function of Thyroid Gland
- the synthesis of thyroid hormones T₃ (triiodothyronine) and T₄ (thyroxine) by the thyroid gland involves trapping and oxidation of iodide, iodination of thyroglobulin, and release of T₃ and T₄
- free T₃ (0.03%) and free T₄ (0.3%) represent the hormonally active fraction of thyroid hormones
- the remaining fraction is bound to thyroxine binding globulin (TBG) and albumin and is biologically inactive
- T₃ is more biologically active (3-8x more potent), but T₄ has a longer half-life
- 85% of T₃ is converted to T₂ or reverse T₃ (RT₃) in the periphery by deiodinases
- RT₃ is metabolically inactive but produced in times of stress to decrease metabolic activity
- most of the plasma T₄ pool is derived from the peripheral conversion of T₃
- calcitonin, a hormone, is also produced in the thyroid, by the parafollicular cells or C cells
- it functions by inhibiting osteoclast activity and increasing renal calcium excretion

Role of Thyroid Hormones
- thyroid hormones act primarily through modifying gene transcription by binding to nuclear receptors
- action of these hormones is diffuse, affecting nearly every organ system
- they produce an increase in basal metabolic rate, including: increased Na'/K' ATPase activity, increased O₂ consumption, increased respiration, heat generation, and increased cardiovascular activity
- also play crucial role during fetal life in both neurological and somatic development

Regulation of Thyroid Function
- extrathyroid
  - stimulation of thyroid by TSH, epinephrine, prostaglandins (cAMP stimulators)
  - T₃ negatively feeds back on anterior pituitary to inhibit TSH and on hypothalamus to inhibit TRH
- intrathyroid (autoregulation)
  - increasing iodide supply inhibits iodide organification, thus decreasing T₃ and T₄ synthesis (Wolff-Chaikoff effect)
  - there is varying thyroid sensitivity to TSH in response to iodide availability
  - increased ratio of T₃ to T₄ in iodide deficiency
  - increased activity of peripheral 5' deiodinase in hypothyroidism increases T₃ production despite low T₄ levels

Tests of Thyroid Function and Structure
TSH
- sensitive TSH (sTSH) is the best test for assessing thyroid function
- hyperthyroidism
  - primary: TSH is low because of negative feedback from increased levels of circulating T₃ and T₄
  - secondary: increased TSH results in increased T₃ and T₄
- hypothyroidism
  - primary: increased TSH (most sensitive test) because of less negative feedback from T₃ and T₄
  - secondary: TSH is low or normal with variable response to TRH depending on the site of the lesion (pituitary or hypothalamic)

Free T₃ and Free T₄
- indications: if secondary or tertiary (hypothalamic) hyper/hypothyroidism is suspected, or if normal TSH levels despite symptoms of hyper/hypothyroidism
- standard assessment of thyroid function measures TSH and if necessary free T₃. Free T₃ should be measured if TSH is suppressed and free T₄ is normal to rule out T₃ toxicity

Thyroid Autoantibodies
- thyroglobulin antibodies (TgAb), thyroid peroxidase antibodies, TSH receptor inhibiting antibodies
  - increased in Hashimoto’s disease; normal variant in 10-20% of individuals
- thyroid stimulating immunoglobulin (TSI)
  - increased in Graves’ disease

Plasma Thyroglobulin
- used to monitor residual thyroid activity post-thyroidectomy, e.g. for thyroid cancer recurrence
- normal or elevated levels may suggest persistent, recurrent or metastatic disease, especially on stimulation

Serum Calcitonin
- not routinely done to investigate thyroid nodules
- ordered if suspicion of medullary thyroid carcinoma or family history of MEN IIa or IIb syndromes
Thyroid Imaging/Scans
- normal gland size 15-20 g (estimated by palpation)
- thyroid U/S
  - to measure size of gland, solid vs. cystic nodule, facilitate fine needle aspirate biopsy (FNAB)
- radioactive iodine thyroid scan (Technetium-99)
  - test of structure: order if there is a thyroid nodule and patient is hyperthyroid with low TSH
  - differentiates between hot (functioning \( \rightarrow \) excess thyroid hormone production) and cold (non-functioning) nodules
  - hot nodule \( \rightarrow \) very low chance malignancy; treat hyperthyroidism
  - cold nodule \( \rightarrow \) \(-5\%\) chance malignancy; further work-up required (U/S and FNAB)
- thyroid U/S
  - to measure size of gland, solid vs. cystic nodule, facilitate fine needle aspirate biopsy (FNAB)
- radioactive iodine uptake (RAIU)
  - test of function: order if patient is thyrotoxic
  - RAIU measures the turnover of iodine by thyroid gland in vivo
  - if \( ^{131}I \) uptake (i.e. incorporated) \( \rightarrow \) gland is overactive (hyperthyroid)
  - if \( ^{131}I \) uptake (i.e. not incorporated) \( \rightarrow \) gland is leaking thyroid hormone (e.g. thyroiditis), exogenous thyroid hormone use, or excess iodine intake (e.g. amiodarone or contrast dye, which has high iodine content)

Thyroid Biopsy
- fine needle aspiration (FNA) for cytology
  - differentiates between benign and malignant disease
  - best done under ultrasound guidance
  - accuracy decreased if nodule is greater than 50% cystic, or if nodule located posteriorly in the gland

Treatment

- thionamides: PTU or MMI; MMI recommended (except in first trimester pregnancy)
- β-blockers for symptom control
- radioactive iodine thyroid ablation for Graves’ disease
- surgery in the form of hemi, sub-total, or complete thyroidectomy

Graves’ Disease

Definition

- syndrome characterized by hyperthyroidism with any of: diffuse goitre, ophthalmopathy, dermopathy

Epidemiology

- most common cause of thyrotoxicosis
- occurs at any age with peak in 3rd and 4th decade
- F > M = 7:1, 1.5-2% of U.S. women
- familial predisposition: 15% of patients have a close family member with Graves’ disease and 50% have family members with positive circulating antibodies
- association with HLA B8 and DR3
- may be associated with other inherited autoimmune disorders (e.g. pernicious anemia, Hashimoto’s disease)

Etiology and Pathophysiology

- autoimmune disorder due to a defect in T-suppressor cells
- B lymphocytes produce TSI that binds the TSH receptor and stimulates the thyroid gland
- immune response can be triggered by postpartum state, iodine excess, lithium therapy, viral or bacterial infections, glucocorticoid withdrawal
- ophthalmopathy a result of increased tissue volume due to inflammation and accumulation of glycosaminoglycans, stimulated by TSI, that increase osmotic pressure within the orbit. This leads to fluid accumulation and displacement of the eye ball forward
- dermopathy may be related to cutaneous glycosaminoglycan deposition

Clinical Features

- signs and symptoms of thyrotoxicosis
- diffuse thyroid goitre ± thyroid bruit secondary to increased blood flow through the gland
- ophthalmopathy: proptosis, diplopia, conjunctival injection, corneal abrasions, periorbital puffiness, lid lag, decreased visual acuity if Graves’ (plus signs of hyperthyroidism: lid retraction, characteristic stare)

Graves’ Ophthalmopathy

NO SPECS (in order of changes usually)
- No signs
- Only signs: lid lag, lid retraction
- Soft tissue: periorbital puffiness, conjunctival injection, chemosis
- Proptosis/Exophthalmos
- Extraocular (diplopia)
- Corneal abrasions (since unable to close eyes)
- Sight loss

Signs and Symptoms of HYPERthyroidism

- Tremor
- Heart rate up
- Yawning (fatigued)
- Restlessness
- Oligomenorrhea/amenorrhea
- Intolerance to heat
- Diarrhea
- Irritability
- Sweating
- Muscle wasting/weight loss

Caution with Thionamides

These drugs are effective in controlling hyperthyroidism and induce permanent remission in 20-30% of patients with Graves’ disease. They inhibit thyroid hormone synthesis. They are most often employed to achieve a euthyroid state before definitive treatment.

Adverse effects include teratogenicity, agranulocytosis, hepatotoxicity and ANCA-positive vasculitis.
• dermatopathy (rare): pretibial myxedema (thickening of dermis that manifests as non-pitting edema)
• acropachy: clubbing and thickening of distal phalanges

Investigations
• low TSH
• increased free \( T_4 \) (and/or increased \( T_3 \))
• positive for TSI
• increased radioactive iodine uptake
• diffuse high uptake on thyroid scan (only do this test in the presence of nodule)

Treatment
• thionamides
  ▪ propylthiouracil (PTU) or methimazole (MMI)
  ▪ inhibit thyroid hormone synthesis by inhibiting peroxidase-catalyzed reactions, thereby inhibiting organification of iodide, blocking the coupling of iodotyrosines. PTU also inhibits peripheral deiodination of \( T_4 \) to \( T_3 \)
  ▪ continue treatment until remission occurs (20–40% of patients achieve spontaneous remission at 6-18 mo of treatment)
  ▪ small goitre and recent onset are good indicators for long-term remission with medical therapy
  ▪ major side effects: hepatitis, agranulocytosis and fever/arthralgias
  ▪ minor side effects: rash
  ▪ iodinated contrast agents: sodium ipodate and iopanoic acid can inhibit conversion of \( T_4 \) to \( T_3 \) and are especially effective in combination with MMI
  ▪ MMI preferred vs. PTU due to longer duration of action (once daily for most), more rapid efficacy, and lower incidence of side effects
  ▪ MMI contraindicated in pregnancy (teratogenic), use PTU
• symptomatic treatment with \( \beta \)-blockers
• thyroid ablation with radioactive \( ^{131}I \) if PTU or MMI trial does not produce disease remission
  ▪ high incidence of hypothyroidism after \( ^{131}I \) requiring lifelong thyroid hormone replacement
  ▪ contraindicated in pregnancy
  ▪ subtotal or total thyroidectomy (indicated rarely for large goiters, suspicious nodule for CA, if patient is intolerant to thionamides and refusing RAI ablation)
    ▪ risks include hypoparathyroidism and vocal cord palsy
  ▪ ophthalmopathy/orbitopathy
    ▪ smoking cessation is most important
    ▪ prevent drying
    ▪ high dose prednisone in severe cases
    ▪ orbital radiation, surgical decompression

Prognosis
• course involves remission and exacerbation unless gland is destroyed by radioactive iodine or surgery
• lifetime follow-up needed
• risk of relapse is 37%, 21%, 6% in thionamides, radioiodine ablation, and surgery groups, respectively

Subacute Thyroiditis (Thyrotoxic Phase)

Definition
• acute inflammatory disorder of the thyroid gland characterized by an initial thyrotoxic state followed by hypothyroidism eventually followed by euthyroidism in most cases
• two subtypes: painful and painless

Etiology and Pathophysiology
• acute inflammation of the thyroid gland characterized by giant cells and lymphocytes
• disruption of thyroid follicles by inflammatory process results in the release of stored hormone rather than excessive production of new thyroid hormone
• painful = viral (usually preceded by URTI), De Quervain’s (granulomatous thyroiditis)
• painless = postpartum, auto-immune, lymphocytic
  ▪ occurs in 5-10% of postpartum mothers and is symptomatic in 1/3 of patients

Clinical Features
• thyroid gland enlargement
• two forms
  ▪ painful ("De Quervain’s") thyroid, ears, jaw and occiput
  ▪ painless ("Silent")
fever and malaise may be present, especially in De Quervain’s postpartum: thyrotoxicosis 2-3 mo postpartum with a subsequent hypothyroid phase at 4-8 mo postpartum may be mistakenly diagnosed as postpartum depression

Laboratory Investigations
- initial elevated free $T_4$, $T_3$, low TSH, RAIU markedly reduced
- marked elevation of ESR in painful variety only
- as disease progresses values consistent with hypothyroidism may appear
- rise in RAIU reflects gland recovery

Treatment
- painful – high dose NSAIDs, prednisone may be required for severe pain, fever, or malaise
- iodinated contrast agents (e.g. iopanoic acid, ipodate) to inhibit peripheral conversion of $T_4$ to $T_3$
- $\beta$-adrenergic blockade is usually effective in reversing most of the hypermetabolic and cardiac symptoms in both subtypes
- if symptomatically hypothyroid, may treat short-term with thyroxine

Prognosis
- full recovery in most cases, but permanent hypothyroidism in 10% of painless thyroiditis
- postpartum: most resolve spontaneously without need for supplementation, however may recur with subsequent pregnancies

Toxic Adenoma/Toxic Multinodular Goitre

Etiology and Pathophysiology
- autonomous thyroid hormone production from a functioning adenoma that is hypersecreting $T_3$ and $T_4$
- may be singular (toxic adenoma) or multiple (toxic multinodular goitre [Plummer’s disease])

Clinical Features
- goitre with adenomatous changes
- tachycardia, heart failure, arrhythmia, weight loss, nervousness, weakness, tremor, and sweats
- atrial fibrillation is a common presentation in the elderly
- seen most frequently in elderly people, often with presentation of atrial fibrillation

Investigations
- low TSH, high $T_3$ and $T_4$
- thyroid scan with increased uptake in nodule(s) and suppression of the remainder of the gland

Treatment
- initiate therapy with PTU or MMI to attain euthyroid state in order to avoid radiation thyroiditis
- use high dose radioactive iodine to ablate tissue over weeks
- $\beta$-blockers often necessary for symptomatic treatment prior to definitive therapy
- surgical excision may also be used as 1st line treatment

Thyrotoxic Crisis/Thyroid Storm

Definition
- acute exacerbation of all of the symptoms of thyrotoxicosis presenting in a life-threatening state secondary to uncontrolled hyperthyroidism – medical emergency!
- rare, but serious with mortality rate between 20-30%

Etiology and Pathophysiology
- often precipitated by infection, trauma, or surgery in a hyperthyroid patient

Differential Diagnosis
- sepsis, pheochromocytoma, malignant hyperthermia, drug overdose, neuroleptic malignant syndrome

Clinical Features
- hyperthyroidism
- extreme hyperthermia, tachycardia, vomiting, diarrhea, vascular collapse, hepatic failure with jaundice, and confusion
- tachyarrhythmia, congestive heart failure, shock
- mental status changes ranging from delirium to coma
Laboratory Investigations
• increased free T\(_3\) and T\(_4\), undetectable TSH
• ± anemia, leukocytosis, hyperglycemia, hypercalcemia, elevated LFTs

Treatment
• principles are the same as in hyperthyroidism except use higher doses and frequencies
• initiate prompt therapy; do not wait for confirmation from lab
• supportive: fluid and electrolytes, diuretics, vasopressors, cooling blanket, and acetaminophen for hyperthermia
• propranolol (IV) for tachycardia and to decrease peripheral conversion of T\(_4\) to T\(_3\) (watch for CHF)
• high dose PTU/MMI
• iodide (NaI, KI, Lugol’s solution) to inhibit release of thyroid hormone, given after PTU
• iodinated radiocontrast solutions such as iopanoic acid inhibit both peripheral conversion of T\(_4\) to T\(_3\) and release of thyroid hormone
• lithium to inhibit release of thyroid hormone
• dexamethasone to block peripheral conversion, to lower body temperature, and to treat possible underlying autoimmune condition
• if extreme plasmapheresis or dialysis to remove high circulating thyroid hormone
• treat precipitant

Prognosis
• probably <20% mortality rate if rapidly recognized and treated

Hypothyroidism

Definition
• clinical syndrome caused by cellular responses to insufficient thyroid hormone production

Epidemiology
• 2-3% of general population
• F:M = 10:1
• 10-20% of women over age 50 have subclinical hypothyroidism (normal T\(_4\), TSH mildly elevated)
• iodine deficiency most common cause worldwide, but not in North America

Etiology and Pathophysiology
• primary hypothyroidism (90%)
  ▪ inadequate thyroid hormone production secondary to intrinsic thyroid defect
  ▪ iatrogenic: post-ablative (\(^{131}\)I or surgical thyroidectomy)
  ▪ autoimmune: Hashimoto’s thyroiditis, chronic thyroiditis, idiopathic, burnt out Graves’
  ▪ hypothyroid phase of subacute thyroiditis
  ▪ drugs: goitrogens (iodine), PTU, MMI, lithium
  ▪ infiltrative disease (progressive systemic sclerosis, amyloid)
  ▪ iodine deficiency
  ▪ congenital (1/4000 births)
  ▪ neoplasia
• secondary hypothyroidism: pituitary hypothyroidism
  ▪ insufficiency of pituitary TSH
• tertiary hypothyroidism: hypothalamic hypothyroidism
  ▪ decreased TRH from hypothalamus (rare)
• peripheral tissue resistance to thyroid hormone (Refetoff syndrome)

Thyroid Hormone Replacement for Subclinical Hypothyroidism

Purpose: To assess the effects of thyroid hormone replacement for subclinical hypothyroidism.

Study Selection: RCTs comparing thyroid hormone replacement with placebo in adults with subclinical hypothyroidism. Minimum duration of follow-up was one month.

Results: No trial assessed (cardiovascular) mortality or morbidity. Seven studies evaluated symptoms, mood and quality of life with no statistically significant improvement. One study showed a statistically significant improvement in cognitive function. Six studies assessed serum lipids, there was a trend for reduction in some parameters following levothyroxine replacement. Some echocardiographic parameters improved after levothyroxine replacement therapy, like myocardial relaxation. Only four studies reported adverse events with no statistically significant differences between groups.

Conclusions: In current RCTs, levothyroxine replacement therapy for subclinical hypothyroidism did not result in improved survival or decreased cardiovascular morbidity. Data on health-related quality of life and symptoms did not demonstrate significant differences between intervention groups. Some evidence indicates that levothyroxine replacement improves some parameters of lipid profiles and left ventricular function.

Signs and Symptoms of Hypothyroidism

Treatment

- L-thyroxine (dose range: 0.05-0.2 mg PO OD – 1.6 µg/kg/d)
- usually require 1.6 times their weight in kg as the dose in µg/d
- elderly patients and those with CAD: start at 0.025 mg daily and increase gradually every 6 wk (start low, go slow)
- after initiating L-thyroxine, TSH needs to be evaluated in 6 wk; dose is adjusted until TSH returns to normal reference range
- once maintenance dose achieved, follow-up TSH with patient annually
- secondary/tertiary hypothyroidism:
  - need to rule out and/or treat adrenal insufficiency first
  - monitor via measurement of free T₄ (TSH is unreliable in this setting)

CONGENITAL HYPOTHYROIDISM

- see Pediatrics, P30

Hashimoto’s Thyroiditis

- most common form of primary hypothyroidism in North America
- chronic autoimmune thyroiditis characterized by both cellular and humoral factors in the destruction of thyroid tissue
- two major forms: goitrous and atrophic; both forms share same pathophysiology but differ in the extent of lymphocytic infiltration, fibrosis, and thyroid follicular cell hyperplasia
- goitrous variant usually presents with a rubbery goitre and euthyroidism, then hypothyroidism becomes evident
  - associated with fibrosis
- atrophic variant patients are hypothyroid from the start
  - associated with thyroid lymphoma

Etiology and Pathophysiology

- defect in clone of T-suppressors leads to cell-mediated destruction of thyroid follicles
- B lymphocytes produce antibodies against thyroid components including thyroglobulin, thyroid peroxidase, TSH receptor, Na⁺/I symporter

Risk Factors

- female gender
- genetic susceptibility: increased frequency in patients with Down’s syndrome, Turner’s syndrome, certain HLA alleles, cytotoxic T-lymphocyte-associated protein 4 (CTLA-4)
- family Hx or personal Hx of other autoimmune diseases
- cigarette smoking
- high iodine intake
- stress and infection

Investigations

- high TSH, low T₄ (not necessary to measure T₃ as it will be low as well)
- presence of thyroid peroxidase and thyroglobulin antibodies in serum

Treatment

- if hypothyroid, replace with L-thyroxine (analog of T₄)
Myxedema Coma

Definition
- severe hypothyroidism complicated by trauma, sepsis, cold exposure, MI, inadvertent administration of hypnotics or narcotics, and other stressful events – medical emergency!
- rare, but serious mortality when it occurs (up to 60%, despite therapy)

Clinical Features
- hallmark symptoms of decreased mental status and hypothermia; hyponatremia, hypotension, hypoglycemia, bradycardia, hypoventilation, and generalized edema often present

Investigations
- decreased T₄, increased TSH, decreased glucose
- check ACTH and cortisol for evidence of adrenal insufficiency

Treatment
- aggressive treatment required
- ABCs: ICU admission
- corticosteroids (for risk of concomitant adrenal insufficiency): hydrocortisone 100 mg q8h
- L-thyroxine 0.2-0.5 mg IV loading dose, then 0.1 mg IV OD until oral therapy tolerated; also consider T₃ therapy
- supportive measures: mechanical ventilation, fluids, vasopressor drugs, passive rewarming, IV dextrose
- monitor for arrhythmia

Sick Euthyroid Syndrome (SES)

Definition
- changes in circulating thyroid hormones amongst patients with serious illness, trauma or stress
- not due to intrinsic thyroid or pituitary disease
- initially low free T₃ may be followed by low TSH and if severe illness low free T₄. With recovery of illness TSH may overshoot and become transiently high

Pathophysiology
- abnormalities in SES include alterations in
  - peripheral transport and metabolism of thyroid hormone
  - regulation of TSH secretion
  - thyroid function itself

Labs
- initially decreased free T₃ followed by decreased TSH and finally decreased free T₄

Treatment
- treat the underlying disease; thyroid hormone replacement worsens outcomes
- thyroid function tests normalize once patient is well (initially with a transient increase in TSH)

Non-Toxic Goitre

Definition
- generalized enlargement of the thyroid gland in a euthyroid individual that does not result from inflammatory or neoplastic processes

Pathophysiology
- the appearance of a goitre is more likely during adolescence, pregnancy, and lactation because of increased thyroid hormone requirements
  - early stages: goitre is usually diffuse
  - later stages: multinodular non-toxic goitre with nodule, cyst formation and areas of ischemia, hemorrhage, and fibrosis

Etiology
- iodine deficiency or excess
- goitrogens: brassica vegetables (e.g. turnip, cassava)
- drugs: iodine, lithium, para-aminosalicylic acid
- any disorder of hormone synthesis with compensatory growth
- peripheral resistance to thyroid hormone
Treatment
- remove goitrogens
- radioiodine therapy (need very high doses since non-toxic, used as last resort)
- suppression with L-thyroxine (rarely done)
- surgery may be necessary for severe compressive symptoms

Complications
- compression of neck structures causing stridor, dysphagia, pain and hoarseness
- multinodular goitre may become autonomous leading to toxic multinodular goitre and hyperthyroidism

Thyroid Nodules

Definition
- clearly defined discrete mass, separated from the thyroid parenchyma
- palpable nodules are found in approximately 5% of the population
- M:F = 1:4

Etiology
- benign tumours (e.g. colloid nodule, follicular adenoma)
- thyroid malignancy
- hyperplastic area in a multinodular goitre
- cyst: true thyroid cyst, area of cystic degeneration in a multinodular goitre

Investigations
- thyroid ultrasound to determine size and characteristics (cystic vs. solid vs. mixed)
- thyroid function tests (TSH)
- thyroid scan only if TSH is low to determine if nodule is hot (i.e. significant $^{131}$I uptake into nodule) which signifies very low malignant potential
- FNA for all nodules >1-1.5 cm, if not a hot nodule

Thyroid Malignancies
- see Otolaryngology OT37

Adrenal Cortex

Adrenocorticotropic Hormone (ACTH)
- a polypeptide (cleaved from prohormone POMC), secreted in a pulsatile fashion from the anterior pituitary with diurnal variability (peak: 0200-0400; trough: 1800-2400)
- secretion regulated by corticotropin-releasing hormone (CRH) and arginine vasopressin (AVP)
- stimulates growth of adrenal cortex and release of glucocorticoids, androgens and, to a limited extent, mineralocorticoids
- some melanocyte stimulating activity

Adrenocortical Hormones

Aldosterone
- a mineralocorticoid which regulates extracellular fluid (ECF) volume through Na⁺ (and Cl⁻) retention and K⁺ (and H⁺) excretion (stimulates distal tubule Na⁺/K⁺ ATPase)
- regulated by the renin-angiotensin-aldosterone system (Figure 10)
- negative feedback to juxtaglomerular apparatus (JGA) by long loop (aldosterone → volume expansion) and short loop (angiotensin II → peripheral vasoconstriction)
Cortisol
- a glucocorticoid, regulated by the HPA axis
- involved in regulation of metabolism; counteracts the effects of insulin
- support blood pressure, vasomotor tone
- also involved in regulation of behaviour and immunosuppression

<table>
<thead>
<tr>
<th>Stimulatory Effects</th>

<td>Inhibit vitamin D₃ and inhibit calcium uptake</td>
</tr>
</tbody>
</table>

Androgens
- sex steroids regulated by ACTH; primarily responsible for adrenarche (growth of axillary and pubic hair)
- principal adrenal androgens are dihydroepiandrosterone (DHEA), androstenedione and 11-hydroxyandrostenedione
- proportion of total androgens (adrenal to gonadal) increases in old age
Adrenocortical Functional Work-Up

STIMULATION TEST
- purpose: diagnosis of hormone deficiencies
- method: measure target hormone after stimulation with tropic (pituitary) hormone

1. Tests of Glucocorticoid Reserve
   - Cosyntropin (ACTH analogue) Stimulation Test
     - give 1 µg or 250 µg cosyntropin IV, then measure plasma cortisol levels at time 0, 30, and 60 min
     - physiologic response: stimulated plasma cortisol of >500 nmol/L (>18 µg/dL)
     - inappropriate response: inability to stimulate increased plasma cortisol
   - insulin tolerance test used to diagnose secondary or tertiary hypoadrenalism (see Pituitary Gland, E16)

SUPPRESSION TESTS
- purpose: diagnosis of hormone hypersecretion
- method: measure target hormone after suppression of its tropic (pituitary) hormone

1. Tests of Pituitary-Adrenal Suppressibility
   - Dexamethasone (DXM) Suppression Test
     - principle: DXM suppresses pituitary ACTH → plasma cortisol should be lowered if HPA axis is normal
     - Screening Test: Overnight DXM Suppression Test
       - oral administration of 1 mg DXM at midnight → measure plasma cortisol levels the following day at 8 am
       - physiologic response: plasma cortisol <50 nmol/L (1.8 µg/dL), with 50-140 nmol/L being a "grey zone" (cannot be certain if normal or not)
       - inappropriate response: failure to suppress plasma cortisol
       - <20% false positive results due to obesity, depression, alcohol, other medications
     - Confirmatory Test: Other testing is used to confirm the diagnosis, such as:
       - 24 h urine free cortisol (shows overproduction of cortisol)
       - midnight salivary cortisol (if available), shows lack of diurnal variation
       - inappropriate response: remains high (normally will be low at midnight)

2. Tests of Mineralocorticoid Suppressibility
   - principle: expansion of extracellular fluid volume (ECFV) → plasma aldosterone should be lowered if HPA axis were normal
   - ECFV Expansion with Normal Saline (NS)
     - IV infusion of 500 mL/h of NS for 4 h → then measure plasma aldosterone levels
     - plasma aldosterone >277 pmol/L (>10 ng/dL) is consistent with primary hyperaldosteronism, <140 pmol/L (<5 ng/dL) is normal
     - inappropriate response: failure to suppress plasma aldosterone
Mineralocorticoid Excess Syndromes

Figure 11. Approach to mineralocorticoid excess syndromes

Definition
- primary hyperaldosteronism (PH): excess aldosterone production (intra-adrenal cause)
- secondary hyperaldosteronism: aldosterone production in response to excess RAAS (extra-adrenal cause)

Etiology
- primary hyperaldosteronism
  - aldosterone-producing adrenal adenoma (Conn’s syndrome)
  - bilateral or idiopathic adrenal hyperplasia
  - glucocorticoid-remediable aldosteronism
  - aldosterone-producing adrenocortical carcinoma
  - unilateral adrenal hyperplasia
- secondary hyperaldosteronism (see Figure 11)

Clinical Features
- hypertension
- hypokalemia (may have mild hypernatremia), metabolic alkalosis
- normal K⁺, low Na⁺ in SH (low effective circulating volume leads to ↑ ADH release) → edema
- increased cardiovascular risk: LV hypertrophy, atrial fibrillation, stroke, MI
- fatigue, weakness, paresthesia, headache; severe cases with tetany, intermittent paralysis

Diagnosis
- investigate plasma aldosterone to renin ratio in patients with hypertension and hypokalemia
- confirmatory testing for PH: aldosterone suppression test (demonstrate inappropriate aldosterone secretion with ECFV expansion)
- imaging: CT adrenal glands

</tbody>
</table>

Treatment
- inhibit action of aldosterone: spironolactone, eplerenone, triamterene, amiloride (act on sodium channels)
- surgical excision of adrenal adenoma
- secondary hyperaldosteronism: treat underlying cause
Cushing's Syndrome

Definition
• results from chronic glucocorticoid excess (endogenous or exogenous sources)

Etiology
• ACTH-dependent (85%) – bilateral adrenal hyperplasia and hypersecretion due to:
  ▪ ACTH-secreting pituitary adenoma (Cushing's disease; 80% of ACTH-dependent)
  ▪ ectopic ACTH-secreting tumour (e.g. small cell lung carcinoma, bronchial, carcinoid, pancreatic islet cell, pheochromocytoma or medullary thyroid tumours)
• ACTH-independent (15%)
  ▪ long-term use of exogenous glucocorticoids
  ▪ primary adrenocortical tumours: adenoma and carcinoma (uncommon)
  ▪ bilateral adrenal nodular hyperplasia

Clinical Features
• symptoms: weakness, insomnia, mood disorders, impaired cognition, easy bruising, oligo-/amenorrhea, hirsutism and acne (ACTH dependent)
• signs: central obesity, round face, supraclavicular and dorsal fat pads, facial plethora, proximal muscle wasting, purple abdominal striae, skin atrophy, acanthosis nigricans, hypertension, hyperglycemia, osteoporosis, pathologic fractures, hyperpigmentation, hyperandrogenism if ACTH-dependent

Treatment
• adrenal
  ▪ adenoma: unilateral adrenalectomy (curative)
  ▪ carcinoma: adjunctive chemotherapy often not useful (frequent metastases, poor prognosis)
  ▪ medical treatment: mitotane, ketoconazole to reduce cortisol
• pituitary
  ▪ trans-sphenoidal resection, with glucocorticoid supplement post-operatively
• ectopic ACTH tumour (paraneoplastic syndrome): usually bronchogenic cancer (poor prognosis)
  ▪ surgical resection, if possible; chemotherapy/radiation for primary tumour
  ▪ agents blocking adrenal steroid synthesis: metyrapone or ketoconazole

Congenital Adrenal Hyperplasia
• see Pediatrics, P31
Hyperandrogenism

Definition
• state of having excessive secretion of androgens (DHEA, DHEA sulfate, testosterone)

Etiology and Pathophysiology

Clinical Features

Females:
• hirsutism
  ▪ male pattern growth of androgen-dependent terminal body hair in women: back, chest, upper abdomen, face, linea alba
  ▪ Ferriman-Gallwey scoring system is used to quantify severity of hirsutism
• virilization
  ▪ masculinization: hirsutism, temporal balding, clitoral enlargement, deepening of voice, acne
  ▪ increase in musculature
• defeminization
  ▪ loss of female secondary sex characteristics (i.e. amenorrhea, ↓ breast size, infertility)

Males:
• minimal effects on hair, muscle mass, etc.
• inhibition of gonadotropin secretion may cause reduction in: testicular size, testicular testosterone production and spermatogenesis

Investigations
• testosterone, DHEA-S as a measure of adrenal androgen production
• LH/FSH (commonly in PCOS > 2.5)
• 17-OH progesterone, elevated in CAH due to 21-OH deficiency
• for virilization: CT/MRI of adrenals and ovaries (identify tumours)
• if PCOS, check blood glucose, lipids, 75 g OGTT

Treatment
• discontinue causative medications
  ▪ antiandrogens, e.g. spironolactone
• oral contraceptives (e.g. cyproterone acetate – blocks androgen receptor; found in Diane 35°)
• surgical resection of tumour
• low dose glucocorticoid ± mineralocorticoid if CAH suspected
• treat specific causative disorders, e.g. tumours, Cushing’s, etc.
• cosmetic therapy (laser, electrolysis)
Adrenocortical Insufficiency

Definition
- a state of inadequate cortisol and aldosterone production by the adrenal glands

Etiology

PRIMARY (ADDISON’S DISEASE)

Table 24. Etiology of Primary Adrenocortical Insufficiency

<table>
<thead>
<tr>
<th>Etiology</th>
<th>Description</th>
</tr>
</thead>
</table>
| Autoimmune (70-90%) | Isolated adrenal insufficiency  
Polyglandular autoimmune syndrome type I and II  
Antibodies often directed against adrenal enzymes and 3 cortical zones |
| Infection         | TB (7-20%) (most common in developing world)  
Fungal: histoplasmosis, panacoccidiomycosis  
HW, CMV  
Syphilis  
African trypanosomiasis |
| Infiltrative      | Metastatic cancer (lung>stomach>esophagus>colon>breast); lymphoma  
Sarcoidosis, amyloidosis, hemochromatosis |
| Vascular          | Bilateral adrenal hemorrhage  
Sepsis (meningococcal, Pseudomonas)  
Coagulopathy in adults or Waterhouse-Friderichsen syndrome in children  
Thrombosis, embolism, adrenal infarction |
| Drugs             | Inhibit cortisol: ketoconazole, megestrol acetate  
Increase cortisol metabolism: rifampin, phenytoin, barbiturates, heparin, coumadin |
| Others            | Adrenoleukodystrophy  
Congenital adrenal hypoplasia (impaired steroidogenesis)  
Familial glucocorticoid deficiency or resistance |

SECONDARY ADRENOCORTICAL INSUFFICIENCY
- inadequate pituitary ACTH secretion
- multiple etiologies (see Hypopituitarism, E20), including withdrawal of exogenous steroids

Clinical Features

Table 25. Clinical Features of Primary and Secondary Adrenal Insufficiency (AI)

High morning plasma ACTH | Insulin tolerance test  
Cosyntropin Stimulation Test  
Low morning plasma ACTH |

Adapted from: Salvatori R. JAMA 2005;294:2481-2488

Treatment
- acute condition – can be life-threatening
  - IV NS in large volumes (2-3 L); add D5W if hypoglycemic from adrenal insufficiency
  - hydrocortisone 50-100 mg IV q6-8h for 24h, then gradual tapering
  - identify and correct precipitating factors
- maintenance
  - hydrocortisone 15-20 mg total daily dose, in 2-3 divided doses, highest dose in the AM
  - Florinef® (fludrocortisone, synthetic mineralocorticoid) 0.05-0.2 mg PO daily if mineralocorticoid deficient increase dose of steroids 2-3 fold for a few days during moderate-severe illness (e.g. with vomiting, fever)
  - major stress (e.g. surgery, trauma) requires 150-300 hydrocortisone IV daily divided into 3 doses
  - medical alert bracelet and instructions for emergency hydrocortisone/dexamethasone IM/SC injection
Adrenal Medulla

Catecholamine Metabolism

• catecholamines are synthesized from tyrosine in postganglionic sympathetic nerves (norepinephrine) and chromaffin cells of adrenal medulla (epinephrine)
• broken down into metanephrines and other metabolites (VMA, HVA) and excreted in urine

Pheochromocytoma

Definition
• rare catecholamine secreting tumour derived from chromaffin cells of the sympathetic system

Epidemiology
• most commonly a single tumour of adrenal medulla
• rare cause of hypertension (<0.2% of all hypertensives)

Etiology and Pathophysiology
• most cases sporadic (80%)
• familial: associated with multiple endocrine neoplasia II (MEN IIA and IIB) (50% penetrance; i.e. 50% of people with the mutation get pheochromocytoma), von Hippel-Lindau (10-20% penetrance), paraganglioma (20% penetrance), or neurofibromatosis type 1 (0.1-5.7% penetrance)
• tumours, via unknown mechanism, able to synthesize and release excessive catecholamines

Clinical Features
• 50% suffer from paroxysmal HTN; the rest have sustained HTN
• classic triad: episodic “pounding” headache, palpitations/tachycardia, diaphoresis
• other symptoms: tremor, anxiety, chest or abdominal pain, nausea/vomiting, visual blurring, weight loss, polyuria, polydipsia
• other signs: orthostatic hypotension, papilledema, hyperglycemia, dilated cardiomyopathy
• symptoms may be triggered by stress, exertion, anesthesia, abdominal pressure, certain foods (especially tyramine containing foods)

Investigations
• urine catecholamines
  ▪ increased catecholamine metabolites (metanephrines) and free catecholamines
  ▪ plasma metanephrines if available (most sensitive)
  ▪ cut-off values will depend on assay used
• CT abdomen
  ▪ if negative, whole body CT and meta-iodo-benzoguanidine (MIBG) scintigraphy, Octreoscan, or MRI

Treatment
• surgical removal of tumour (curative) with careful pre- and post-operative ICU monitoring
• adequate pre-operative preparation
  ▪ α-blockade for BP control; phenoxybenzamine (10-21 d pre-operative), IV phentolamine (peri-operative, if required)
  ▪ β-blockade for HR control once α blocked for a few days
  ▪ metyrosine (catecholamine synthesis inhibitor) + phenoxybenzamine or prazosin
  ▪ volume restoration with vigorous salt-loading and fluids
• rescreen urine 1-3 mo post-operatively
• screen urine in first degree relatives; genetic testing in patients <50 yr old

Disorders of Multiple Endocrine Glands

Multiple Endocrine Neoplasm (MEN)

• neoplastic syndromes involving multiple endocrine glands
• tumours of neuroectodermal origin
• autosomal dominant inheritance with variable penetrance
• genetic screening for RET proto-oncogene on chromosome 10 has long-term benefit in MEN II
  ▪ early cure and prevention of medullary thyroid cancer

Investigations

- **MEN I**
  - laboratory
    - may consider genetic screening for MEN-1 mutation in index patients
      - if a mutation is identified, screen family members who are at risk
    - gastrinoma: elevated serum gastrin level (>200 ng/mL) after IV injection of secretin
    - insulinoma: reduced fasting blood glucose (hypoglycemia) with elevated insulin and C-peptide levels
    - glucagonoma: elevated blood glucose and glucagon levels
    - pituitary tumours: assess GH, IGF-1 and prolactin levels (for over-production), TSH, free T<sub>3</sub>, 8 AM cortisol, LH, FSH, bioavailable testosterone or estradiol (for underproduction due to mass effect of tumour)
    - hyperparathyroidism: serum Ca<sup>2+</sup> and albumin, PTH levels; bone density scan (DEXA)
  - imaging
  - MRI for pituitary tumours, gastrinoma, insulinoma

- **MEN II**
  - laboratory
    - genetic screening for RET mutations in all index patients
      - if a mutation is identified screen family members who are at risk
    - calcitonin levels (MTC); urine catecholamines and metanephrines (pheochromocytoma); serum Ca<sup>2+</sup>, albumin and PTH levels (hyperparathyroidism)
    - pentagastrin ± calcium stimulation test if calcitonin level is within reference range
    - FNA for thyroid nodules → cytology
  - imaging
    - CT or MRI of adrenal glands, metaiodobenzylguanidine (MIBG) scan for pheochromocytoma
    - octreoscan and/or radionuclide scanning for determining the extent of metastasis

Treatment

- **MEN I**
  - medical
    - proton pump inhibitor (PPI) for acid hypersecretion in gastrinoma
    - cabergoline or other dopamine agonists to suppress prolactin secretion
    - somatostatin for symptomatic carcinoid tumours

- **MEN II**
  - medical
    - surgery for thyrotoxicosis
    - radioactive iodine (131I) with or without total thyroidectomy
    - total thyroidectomy (less common than 131I) for thyroid nodules and DTC

- surgery for hyperparathyroidism, insulinoma, glucagonoma, pituitary tumours (if medical treatment fails for the latter)
- trans-sphenoidal approach with prn external radiation
- MEN II
- surgery for MEN IIa with pre-operative medical therapy:
  - prostaglandin inhibitors to alleviate diarrhea associated with thyroid cancer
  - α-blocker for at least 10-21 d for pheochromocytoma pre-op
  - hydration, calcitonin, IV bisphosphonates for hypercalcemia

### Calcium Homeostasis

- normal total serum Ca\(^{2+}\): 2.2-2.6 mmol/L (8.5-10.5 mg/dL)
- ionic/free Ca\(^{2+}\) levels: 1.15-1.31 mmol/L (4.6-5.25 mg/dL)
- serum Ca\(^{2+}\) is about 50% protein bound (mostly albumin)
- regulated mainly by two factors: parathyroid hormone (PTH) and vitamin D
- actions mainly on three organs: GI tract, bone, and kidney

#### Table 27. Major Regulators in Calcium Homeostasis

<table>
<thead>
<tr>

</tbody>
</table>
**Hypercalcemia**

**Definition**
- total corrected serum Ca\(^{2+}\) >2.6 mmol/L (10.5 mg/dL) OR ionized Ca\(^{2+}\) >1.35 mmol/L (5.4 mg/dL)

**Approach to Hypercalcemia** (Figure 15)
1. Is the patient hypercalcemic? (correct for albumin – see sidebar)
2. Is the PTH high/normal or low?
3. If PTH is low, is phosphate high/normal or low? If phosphate is high/normal is the level of vitamin D metabolites high or low?

**Clinical Features**
- symptoms depend on the absolute Ca\(^{2+}\) value and the rate of its rise (may be asymptomatic)

**Table 28. Symptoms of Hypercalcemia**

**High Ca\(^{2+}\)**
- Initial investigations: PTH, PO\(_4\), Mg\(^{2+}\), Urine Ca\(^{2+}\), creatinine
- Drugs: Lithium, Oral Calcidiol (25-OH Vit D), Oral Calcitriol (1,25-(OH)\(_2\) Vit D)

**Low Vit D metabolites**
- Hyperparathyroidism: Solitary adenoma (81%), Hyperplasia (15%), Carcinoma (4%), MEN I and IIa
- Tertiary Hyperparathyroidism: Increased PTH after prolonged secondary hyperparathyroidism due to renal failure

**Hypervitaminosis D:** Excessive intake of Vit D or its metabolites
- Nephrotic syndrome, metabolic alkalosis and renal insufficiency
- Drugs: theophylline, thiazide diuretics, estrogen/tamoxifen

**Granulomatous disease:** e.g. TB, sarcoid, lymphoma (esp. Hodgkins) which causes extra-renal production of calcitriol by macrophages in the lung and lymph nodes

**Immobilization**
- Malignancy
  - High bone turnover: e.g. hyperparathyroidism A, thyrotoxicosis, Paget’s disease
  - Milk alkali syndrome: (hypercalcemia, metabolic alkalosis and renal insufficiency)
- Drugs: theophylline, thiazide diuretics, estrogen/tamoxifen

**Hypervitaminosis D:** Excessive intake of Vit D or its metabolites

**Clinical Features**
- symptoms depend on the absolute Ca\(^{2+}\) value and the rate of its rise (may be asymptomatic)

</table>

**Treatment**
- treatment depends on the Ca\(^{2+}\) level and the symptoms
- treat acute, symptomatic hypercalcemia aggressively

**Hypercalcemic crisis (usually >4 mmol/L or 16 mg/dL):** primary symptoms include oliguria/anuria and mental status changes (including somnolence and eventually coma) → this is a medical emergency and should be treated immediately!
**Table 29. Treatment of Acute Hypercalcemic Crisis**

**Approach to Hypocalcemia** (Figure 16)
1. Is the patient hypocalcemic?
2. Is the PTH high or low?
3. If PTH is high, is phosphate low or normal?
4. Is the Mg²⁺ level low?

**Approach to Treatment**
- correct underlying disorder
- mild/asymptomatic (ionized Ca²⁺ >0.8 mmol/L, 3.2 mg/dL)
  - treat by increasing dietary Ca²⁺ by 1000 mg/d |
  - calcitriol 0.25 µg/d |
- acute/asymptomatic hypocalcemia (ionized Ca²⁺ <0.7 mmol/L, 2.8 mg/dL)
  - immediate treatment required |
  - IV calcium gluconate 1-2 g over 10-20 min followed by slow infusion if necessary |
  - goal is to raise Ca²⁺ to low normal range (2.0-2.1 mmol/L, 8.0-8.4 mg/dL) to prevent symptoms but allow maximum stimulation of PTH secretion |
  - if PTH recovery not expected, requires long-term therapy with calcitriol and calcium |
- do not correct hypocalcemia if asymptomatic and suspected to be transient

**Differential Diagnosis of Hypercalcemia**
- Primary hyperparathyroidism |
- Malignancy: hematologic, humoral, skeletal metastases (>90% from 1 or 2) |
- Renal disease: tertiary hyperparathyroidism |
- Drugs: calcium carbonate, milk-alkali syndrome, thiazide, lithium, theophylline, vitamin A/D intoxication |
- Familial hypercalcemic hypercalciuria |
- Granulomatous disease: sarcoidosis, TB, Hodgkin’s lymphoma |
- Thyroid disease: thyrotoxicosis |
- Adrenal disease: adrenal insufficiency, pheochromocytoma |
- Immobilization

**Acute Management of Hypercalcemia/Hypercalcemic Crisis**
- Volume expansion (e.g. NS IV 300-500 cc/h) initial therapy |
- Calcitriol: transient, partial response |
- Bisphosphonate: treatment of choice |
- Corticosteroid: most useful in Vit D toxicity, granulomatous disease, some malignancies |
- Saline diuresis + loop diuretic (for volume overload): temporary measure

**Hypomagnesemia can impair PTH secretion and action.**

**Differential Diagnosis of Tetany**
- Hypocalcemia |
- Metabolic alkalosis (with hyperventilation) |
- Hypokalemia |
- Hypomagnesemia

**Signs and Symptoms of Acute Hypocalcemia**
- Paresthesias: perioral, hands and feet |
- Chvostek’s sign: percussion of the facial nerve just anterior to the external auditory meatus elicits ipsilateral spasm of the orbicularis oculi or orbicularis oris muscles |
- Trousseau’s sign: inflation of a blood pressure cuff above systolic pressure for 3 min elicits carpal spasm and paresthesia
**Hyperphosphatemia**

**Definition**
- serum phosphate $>1.45$ mmol/L (4.1 mg/dL)

**Table 31. Etiology of Hyperphosphatemia**

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

**Clinical Features**
- non-specific, include ectopic calcification, renal osteodystrophy

**Treatment**
- acute: hemodialysis if symptomatic
- chronic: low PO$_4^{3-}$ diet, phosphate binders (e.g. CaCO$_3$)

**Hypophosphatemia**

**Definition**
- serum phosphate $<0.85$ mmol/L (2.4 mg/dL)

**Table 32. Etiology of Hypophosphatemia**

</tr>
</tbody>
</table>

Symptoms usually present when phosphate $<0.32$ mmol/L (1.0 mg/dL)
- Treat asymptomatic patients if phosphate $<0.84$ mmol/L (2.0 mg/dL)
Clinical Features  
- non-specific (CHF, coma, hypotension, weakness, defective clotting)

Treatment  
- treat underlying cause  
  - Oral PO₄³⁻: 2-4 g/d divided bid-qid (start at 1 g/d to minimize diarrhea)  
  - IV PO₄³⁻: only for severely symptomatic patients or inability to tolerate oral therapy

Hypermagnesemia  

Definition  
- serum magnesium >0.85 mmol/L (2.1mg/dL)

Etiology  
- AKI/CRF  
- Mg²⁺-containing antacids or enemas  
- IV administration of large doses of MgSO₄ (e.g. for preeclampsia; see Obstetrics, OB16)

Clinical Features  
- drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest

Treatment  
- discontinue Mg²⁺-containing products  
- IV calcium (Mg²⁺-antagonist) for acute reversal of magnesium toxicity  
- dialysis if renal failure

Hypomagnesemia  

Definition  
- serum magnesium <0.70 mmol/L (1.7 mg/dL)

Etiology  
- GI losses  
  - starvation/malabsorption  
  - vomiting/diarrhea  
  - alcoholism  
  - acute pancreatitis  
- excess renal loss  
  - 2° hyperaldosteronism due to cirrhosis and CHF  
  - hyperglycemia  
  - hypokalemia  
  - hypercalcemia  
  - loop and thiazide-type diuretics  
  - nephrotoxic medications  
  - proton-pump inhibitors

Clinical Features  
- seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities) and arrhythmias including Torsades de pointes

Treatment  
- treat underlying cause  
- Mg²⁺ 1M/IV; cellular uptake of Mg²⁺ is slow, therefore repletion requires sustained correction  
- discontinue diuretics  
  - in patients requiring diuretics, use a K⁺-sparing diuretic to minimize magnesuria

Metabolic Bone Disease  

Osteoporosis  

Definition  
- a condition characterized by decreased bone mass and microarchitectural deterioration of bone tissue with a consequent increase in bone fragility and susceptibility to fracture  
- bone mineral density (BMD) ≥2.5 standard deviations below the peak bone mass for young adults (i.e. T-score ≤–2.5)  
- osteopenia: BMD with T-score between -1.0 and -2.5

Etiology and Pathophysiology  

Primary Osteoporosis  
- primary type 1: most common in post-menopausal women, due to decline in estrogen, worsens with age  
- primary type 2: occurs after age 75, seen in females and males at 2:1 ratio, possibly due to zinc deficiency
Secondary Osteoporosis
- gastrointestinal diseases
- gastrectomy
- malabsorption (e.g. celiac disease)
- chronic liver disease
- bone marrow disorders
- multiple myeloma
- lymphoma
- leukemia
- endocrinopathies
- Cushing's syndrome
- hyperparathyroidism
- hyperthyroidism
- premature menopause
- diabetes
- malignancy
- secondary to chemotherapy
- myeloma

Clinical Features
- commonly asymptomatic
- height loss due to collapsed vertebrae
- fractures: most commonly in hip, vertebrae, humerus and wrist
  - fragility fractures: fracture with fall from standing height
  - Dowager's hump: collapse fracture of vertebral bodies in mid-dorsal region
  - x-ray: vertebral compression and crush fractures, wedge fractures, "codfishing" sign
    (weakening of subchondral plates and expansion of intervertebral discs)
- pain, especially backache, associated with fractures

Approach to Osteoporosis
1. Assess risk factors for osteoporosis on history and physical
2. Decide if patient requires BMD testing with dual-energy x-ray absorptiometry (DEXA): men and women ≥65 yr or younger if presence of risk factors (Table 33)
3. Initial investigations:
   - all patients with osteoporosis: calcium corrected for albumin, CBC, creatinine, ALP, TSH
   - also consider serum and urine protein electrophoresis, celiac workup and 24 h urinary Ca²⁺ excretion to rule out additional secondary causes
   - 25-OH-Vitamin D level should only be measured after 3-4 mo of adequate supplementation and should not be repeated if an optimal level ≥75 nmol/L is achieved
   - lateral thoracic and lumbar x-ray if clinical evidence of vertebral fracture
4. Assess 10-yr fracture risk by combining BMD result and risk factors (only if ≥50 yr)
   1) WHO Fracture Risk Assessment Tool (FRAX);
   2) Canadian Association of Radiologists and Osteoporosis Canada Risk Assessment Tool (CAROC)
   - approach to management guided by 10-yr risk stratification into low, medium, high risk
5. For all patients being assessed for osteoporosis, encourage appropriate lifestyle changes (see Table 35)

**Drug Therapy**

| Bisphosphonate: Inhibitors of osteoclast binding | 1st line in prevention of hip, nonvertebral and vertebral # (Grade A): alendronate, risedronate, zoledronic acid |
| Parathyroid Hormone | YES fragility #: 18-24 mo duration |
| Calcitonin (2nd line): osteoclast receptor binding | YES fragility #: Calcitonin 200 IU nasally OD with Calcitriol 0.25 µg bid |

**Treatment specific to post-menopausal women**

| SERM (selective estrogen-receptor modulator): agonistic effect on bone but antagonistic effect on uterus and breast | 1st line in prevention of vertebral # (Grade A): raloxifene |
| +ve: prevents osteoporotic # (Grade A to B evidence), improves lipid profile, decreased breast ca risk | +ve: increased risk of DVT/PE, stroke mortality, hot flashes, leg cramps |
| -ve: combined estrogen/progestin prevents hip, vertebral, total # | For most women, risks > benefits |
| **HRT: combined estrogen + progesterone (see Gynecology, CY53)** | +ve: increased risks of breast ca, cardiovascular events and DVT/PE |

**Clinical Signs of Fractures or Osteoporosis**

- **Height loss ≥3 cm (Sn 92%)**
- **Weight <51 kg**
- **Kyphosis (Sp 92%)**
- **Tooth count <20 (Sp 92%)**
- **Grip strength**
- **Armspan-height difference >5 cm (Sp 76%)**
- **Wall-occpit-height difference >0 cm (Sp 87%)**
- **Rib-pelvis distance ≤2 fingerbreadth (Sn 88%)**
**Osteomalacia and Rickets**

- **rickets**: osteopenia with disordered calcification leading to a higher proportion of osteoid (unmineralized) tissue *prior* to epiphyseal closure (in childhood)
- **osteomalacia**: osteopenia with disordered calcification leading to a higher proportion of osteoid (unmineralized) tissue *after* epiphyseal closure (in adulthood)

**Etiology and Pathophysiology**

**Vitamin D Deficiency**
- deficient uptake or absorption
  - nutritional deficiency
  - malabsorption: post-gastrectomy, small bowel disease (e.g. Celiac sprue), pancreatic insufficiency
- defective 25-hydroxylation
  - liver disease
  - anticonvulsant therapy
- loss of vitamin D binding protein
- defective 1-α-25 hydroxylation
  - hypoparathyroidism
  - renal failure
- pathophysiology: leads to secondary hyperparathyroidism and hypophosphatemia

**Mineralization Defect**
- abnormal matrix
  - osteogenesis imperfecta
  - fibrogenesis imperfecta
  - axial osteomalacia
- enzyme deficiency
  - hypophosphatasia (inadequate ALP bioactivity)
  - presence of calcification inhibitors
  - bisphosphonates, aluminum, high dose fluoride, anticonvulsants

</tbody>
</table>

- radiologic findings
  - pseudofractures, fissures, narrow radiolucent lines – thought to be healed stress fractures or the result of erosion by arterial pulsation
  - loss of distinctness of vertebral body trabeculae; concavity of the vertebral bodies
  - changes due to secondary hyperparathyroidism: subperiosteal resorption of the phalanges, bone cysts, resorption of the distal ends of long bones
  - others: bowing ofibia, coxa profunda hip deformity
- bone biopsy: usually not necessary but considered the gold standard for diagnosis

**Treatment**
- definitive treatment depends on the underlying cause
- vitamin D supplementation
- PO43− supplements if low serum PO43−, Ca2+ supplements for isolated calcium deficiency
- bicarbonate if chronic metabolic acidosis
Renal Osteodystrophy

- changes to mineral metabolism and bone structure secondary to chronic kidney disease
- represents a mixture of four types of bone disease:
  - osteomalacia: low bone turnover combined with increased unmineralized bone (osteoid)
  - adynamic bone disease: low bone turnover due to excessive suppression of parathyroid gland
  - osteitis fibrosa cystica: increased bone turnover due to secondary hyperparathyroidism
  - mixed uremic osteodystrophy: both high and low bone turnover, characterized by marrow fibrosis and increased osteoid
- metastatic calcification secondary to hyperphosphatemia may occur

Pathophysiology

- metabolic bone disease secondary to chronic renal failure
- combination of hyperphosphatemia (inhibits 1,25(OH)$_2$-Vit. D synthesis) and loss of renal mass (reduced 1-α-hydroxylase)

Clinical Features

- soft tissue calcifications → necrotic skin lesions if vessels involved
- osteodystrophy → generalized bone pain and fractures
- pruritus
- neuromuscular irritability and tetany may occur
- radiologic features of osteitis fibrosa cystica, osteomalacia, osteosclerosis, osteoporosis

Investigations

- serum Ca$^{2+}$ corrected for albumin, PO$_4^{3-}$, PTH, ALP, ± imaging (x-ray, BMD), ± bone biopsy

Treatment

- prevention
  - maintenance of normal serum Ca$^{2+}$ and PO$_4^{3-}$ by restricting PO$_4^{3-}$ intake to 1 g OD
  - Ca$^{2+}$ supplements; PO$_4^{3-}$ binding agents (calcium carbonate, aluminum hydroxide)
  - vitamin D with close monitoring to avoid hypercalcemia and metastatic calcification

Paget’s Disease of Bone

Definition

- a metabolic disease characterized by excessive bone destruction and repair

Epidemiology

- a common disease: 5% of the population, 10% of population >80 yr old

Etiology and Pathophysiology

- postulated to be related to a slow progressing viral infection of osteoclasts, possibly paramyxovirus
- strong familial incidence
- initiated by increased osteoclastic activity leading to increased bone resorption; osteoblastic activity increases in response to produce new bone that is structurally abnormal and fragile

Differential Diagnosis

- primary bone lesions
  - osteogenic sarcoma
  - multiple myeloma
  - fibrous dysplasia
- secondary bone lesions
  - osteitis fibrosa cystica
  - metastases

Clinical Features

- usually asymptomatic (routine x-ray finding or elevated ALP)
- severe bone pain (e.g. pelvis, femur,ibia) is often the presenting complaint
- skeletal deformities: bowed tibias, kyphosis, frequent fractures
- skull involvement: headaches, increased hat size, deafness
- increased warmth over involved bones due to increased vascularity
- high output congestive heart failure
- hypercalcemia with immobilization
- osteosarcoma

Comparison of a Single Infusion of Zoledronic Acid with Risedronate for Paget’s Disease

Study: Two identical, randomized, double-blind, actively controlled trials (combined for analysis).
Patients: 357 men and women who were older than 30 yr of age and had radiologically confirmed Paget’s disease. All but 4 patients had alkaline phosphatase levels that were more than twice the upper limit of normal.
Intervention: One 15-min infusion of 5 mg of zoledronic acid compared with 60 d of oral risedronate (50 mg/d) with follow up at 6 mo.
Primary Outcome: Rate of therapeutic response at 6 mo, defined as a normalization of alkaline phosphatase levels or a reduction of at least 75% in the total alkaline phosphatase excess.
Results: At 6 mo, 96% of patients receiving zoledronic acid had a therapeutic response (169 of 176), as compared with 74.3% of patients receiving risedronate (127 of 171, P<0.001). Alkaline phosphatase levels normalized in 86.6% of patients in the zoledronic acid group and 57.9% of patients in the risedronate group (P<0.001). Zoledronic acid was associated with a shorter median time to a first therapeutic response (169 of 176) as compared with 74.3% of patients receiving risedronate (127 of 171, P<0.001). Alkaline phosphatase levels normalized in 86.6% of patients in the zoledronic acid group and 57.9% of patients in the risedronate group (P<0.001). Zoledronic acid was associated with a shorter median time to a first therapeutic response (64 vs. 89 d, P<0.001). Quality of life increased significantly from baseline at both 3 and 6 mo in the zoledronic acid group and differed significantly from those in the risedronate group at 3 mo. Pain scores improved in both groups. During post-trial follow-up (median, 190 d), 21 of 82 patients in the risedronate group had a loss of therapeutic response, as compared with 1 of 113 patients in the zoledronic acid group (P<0.001).
Conclusions: A single infusion of zoledronic acid produces more rapid, more complete, and more sustained responses in Paget’s disease than does daily treatment with risedronate.
Investigations
- laboratory
  - ↑↑ serum ALP (unless burnt out), Ca\(^{2+}\) normal or ↑, PO\(_4^{3-}\) normal
  - urinary hydroxyproline ↑ (indicates resorption)
- imaging
  - bone scan to evaluate the extent of disease
  - skeletal survey: involved bones are denser and expanded with cortical thickening
    - initial lesion may be destructive and radiolucent
    - multiple fissure fractures in long bones

Complications
- local
  - fractures; osteoarthritis
  - cranial nerve compression and palsies (e.g. deafness), spinal cord compression
  - osteosarcoma/sarcomatous change in 1-3%
    - indicated by marked bone pain, new lytic lesions and sudden increased ALP
- systemic
  - hypercalcemia and nephrolithiasis
  - high output congestive heart failure due to increased vascularity

Treatment
- symptomatic therapy (pain management)
- weight-bearing exercise
- adequate calcium and vitamin D intake to prevent development of secondary hyperparathyroidism
- treat medically if ALP > 3x normal
  - bisphosphonates, e.g. alendronate 40 mg PO OD x 6 mo OR risedronate 30 mg PO OD x 3 mo OR zoledronic acid 5 mg IV per year
  - calcitonin 50-100 U/d SC
- surgery for fractures, deformity, degenerative changes

Male Reproductive Endocrinology

Androgen Regulation
- negative feedback may occur by androgens directly or after conversion to estrogen
  - testosterone (from Leydig cells) primarily involved in negative feedback on LH and GnRH, whereas inhibin (from Sertoli cells) suppresses FSH secretion

Tests of Testicular Function
- testicular size (lower limit = 4 cm x 2.5 cm)
- LH, FSH, total and/or bioavailable testosterone
- human chorionic gonadotropin (hCG) stimulation test
  - assesses ability of Leydig cell to respond to gonadotropin
- semen analysis
  - semen volume, sperm count, morphology and motility
- testicular biopsy
  - indicated with normal FSH and azoospermia/oligospermia

Hypogonadism and Infertility
- see Urology, U34
- deficiency in gametogenesis or testosterone production

Etiology
- causes include primary (testicular failure), secondary (hypothalamic-pituitary failure) and idiopathic
- primary hypogonadism is more common than secondary
Table 38. Classification and Features of Hypogonadism

**Treatment**
- testosterone replacement (improve libido, muscle mass, strength, hair growth, bone mass)
- IM injection, transdermal testosterone patch/gel, oral
- side effects: acne, fluid retention, erythrocytosis, sleep apnea, benign prostatic hypertrophy
- contraindicated if history of prostate cancer
- GnRH agonist to restore fertility, if hypothalamic dysfunction with intact pituitary
- administered SC in pulsatile fashion using an external pump
- hCG ± human menopausal gonadotropin (hMG) (to supply FSH) can be used to restore fertility in cases of either hypothalamic or pituitary lesions
- surgery – only if testicular tissues are not functioning

**Other Causes of Male Infertility**
- hereditary disorders: Kartagener syndrome, cystic fibrosis
- anatomy: hypospadias, retrograde ejaculation
- obstruction: vasal occlusion, vasal aplasia, vasectomy, seminal vesicle disease
- sexual dysfunction: erectile dysfunction, premature ejaculation, infrequent coitus
- surgery: TURP, radical prostatectomy, orchietomy

**DEFECTS IN ANDROGEN ACTION**

**Etiology**
- complete androgen insensitivity (testicular feminization)
- incomplete androgen insensitivity
  - 5α-reductase deficiency
  - mixed gonadal dysgenesis
  - defects in testosterone synthesis
- infertile male syndrome
- undervirilized fertile male syndrome

**Clinical Features**
- depends on age of onset

Adapted from UptoDate, 2010 + Cecil's Essentials of Medicine

Treatment
- appropriate gender assignment in the newborn
- hormone replacement or supplementation
- psychological support
- gonadectomy for cryptorchidism (due to increased risk for testicular cancer)
- reduction mammoplasty for gynecomastia

Erectile Dysfunction

- see Urology, U30

Gynecomastia

Definition
- true gynecomastia refers to benign proliferation of the glandular component of the male breast, resulting in the formation of a concentric, rubbery, firm mass extending from the nipple(s)
- pseudogynecomastia or lipomastia refers to enlargement of soft adipose tissue, especially seen in obese individuals and does not warrant further evaluation

Etiology

Physiologic
- puberty
- elderly (involutional)
- neonatal (maternal hormone)

Pathologic
- endocrinopathies: primary or secondary hypogonadism, hyperthyroidism, extreme hyperprolactinemia, adrenal disease
- tumours: pituitary, adrenal, testicular, breast, ectopic production of hCG
- chronic diseases: cirrhosis, renal, malnutrition (with refeeding)
- drugs: estrogens and estrogen agonists, spironolactone, ketoconazole, cimetidine, digoxin, chemotherapy, marijuana, alcohol
- congenital/genetic: Klinefelter’s syndrome, androgen insensitivity
- other: idiopathic, familial

Pathophysiology
- decreased androgen production + increased estrogen production
- increased availability of estrogen precursors for peripheral conversion to estrogen
- androgen receptor blockage + binding of androgen to sex hormone binding globulin (SHBG)

History
- recent change in breast characteristics
- trauma to testicles
- mumps
- alcohol and/or drug use
- FHx
- sexual dysfunction

Occurrence of Gynecomastia

Causes of Gynecomastia

DOC TECH
- Drugs
- Other
- Congenital
- Tumour
- Endocrine
- CHronic disease
Physical Exam
• signs of feminization
• breast
  ▪ must differentiate from breast cancer (unilateral, eccentric, hard/firm mass, fixed to
    underlying tissue) with possible skin changes (dimpling, retraction) or nipple changes
    (discharge, crusting)
  ▪ gynecomastia occurs concentrically around nipple, is not fixed to underlying tissue, and no
    discrete mass is palpable
• genito-urinary exam
• stigmata of liver or thyroid disease

Investigations
• laboratory: serum TSH, PRL, LH, FSH, testosterone, estradiol, LFTs, creatinine, hCG (if hCG is
  elevated need to locate the primary tumour)
• CXR and CT of chest/abdomen/pelvis (to locate neoplasm)
• testicular U/S to rule out testicular mass
• MRI of hypothalamic-pituitary region if pituitary adenoma suspected

Treatment
• initial observation for most men with gynecomastia
• medical
  ▪ correct the underlying disorder, discontinue responsible drug
  ▪ androgens for hypogonadism
  ▪ anti-estrogens: tamoxifen, clomiphene
• surgical
  ▪ usually required for macromastia; gynecomastia present for >1 yr (fibrosis is unresponsive to
    medication); or failed medical treatment and for cosmetic purposes

Female Reproductive Endocrinology

• see Gynecology, GY4
Paraneoplastic Syndrome

- clinical syndromes involving non-metastatic systemic effects that accompany malignant disease
- triggered by antibodies against neoplasm cross-reacting with normal tissue or by production of a physiologically active substance by the neoplasm
- commonly present with cancers of lung, breast, ovaries, or lymphatic system

Table 40. Clinical Presentation

Investigations
- CBC, electrolytes, creatinine, LFTs, ALP, ESR, C-reactive protein, serum/urine electrophoresis, 
- serum autoantibodies, lumbar puncture 
- imaging: skeletal survey, CT, MRI, PET scan 
- ± endoscopy

Treatment
- treat underlying tumour: surgery, radiation, chemotherapy 
- treat immune-mediated disorder: IVIG, steroids, immunosuppressive drugs, plasmapheresis (reserved for patients with identifiable antibodies in serum)

paroxysmal nocturnal dyspnea
proton pump inhibitor
purified protein derivative
post-traumatic stress disorder
PUD  peptic ulcer disease
PVD  peripheral vascular disease
RCT  randomized controlled trial
SAH  subarachnoid hemorrhage
SDBI  selective serotonin reuptake inhibitor
SERM  selective estrogen receptor modulator
SIDS  sudden infant death syndrome
SLE  systemic lupus erythematosis
SNRI  serotonin noradrenaline reuptake inhibitor
SSRI  selective serotonin reuptake inhibitor
transient ischemic attack
total cholesterol
TC  total cholesterol
TCA  tricylic antidepressant
glucocorticoid
TNF  tissue necrosis factor
TM  tympanic membrane
TMJ  temporomandibular joint
UC  ulcerative colitis
URTI  upper respiratory tract infection
UTI  urinary tract infection
VAIN  vaginal intraepithelial neoplasia
VIN  vulvar intraepithelial neoplasia
VSI  vertebral insufficiency
WSIB  Workplace Safety and Insurance Board
Four Principles of Family Medicine

College of Family Physicians of Canada Guidelines
1. The family physician is a skilled clinician
   - in diagnosing and managing diseases common to the population served
   - recognizes importance of early diagnosis of serious life-threatening illnesses
2. Family medicine is a community-based discipline
   - provides information and access to community services
   - responds/adapts to changing needs and circumstances of the community
3. The family physician is a resource to a defined practice population
   - serves as a health resource
   - advocates for public policy to promote health
4. The patient-physician relationship is central to the role of the family physician
   - committed to the person, not just the disease
   - promotes continuity of patient care

Periodic Health Examination (PHE)

- Canadian Task Force on Preventive Health Care established in 1976, first published in 1979, last updated in 2005
- mandate: to develop and disseminate clinical practice guidelines for primary and preventive care
- recommendations are based on systematic analysis of scientific evidence
  - most notable recommendation is the abolition of the annual physical exam; replaced by the PHE

Purpose of the PHE

- primary prevention: identify risk factors for common diseases; counsel patients to promote healthy behaviour
- secondary prevention: presymptomatic detection of disease to allow early treatment and to prevent disease progression
- update clinical data
- enhance patient-physician relationship

### Breast Cancer Screening Guidelines

**2011 Recommendations on screening for breast cancer in average-risk women** *(The Canadian Task Force on Preventative Health Care)* *(Weak recommendations with low-moderate quality evidence)*

- average-risk women: women age 40-74 with no personal history of breast cancer, history of breast cancer in 1st degree relatives, known mutations of the *BRCA1/BRCA2* genes or previous exposures of the chest wall to radiation

#### Mammography
- age 40-49: no routine screening
- age 50-69: routine screening q2-3yr
- age 70-74: routine screening q2-3yr

#### Magnetic Resonance Imaging (MRI)
- no routine screening with MRI scans

#### Clinical Breast Examination (CBE)
- no routine CBE alone or in conjunction with mammography to screen for breast cancer

#### Breast self-examination
- recommend not advising women to routinely practice breast self-examination

**Classification of recommendation in brackets. See sidebar on FM3.**
**Reference:** Canadian Task Force on Preventative Health Care, 2005

---

**Folic Acid Supplementation in Pregnancy (Joint SOGC-Motherisk clinical guideline)**
- To prevent neural tube defects in all women capable of becoming pregnant
- Low risk women (no personal health risks, planned pregnancy): 0.4-1.0 mg daily folic acid supplementation for at least 2-3 mo before conception and throughout pregnancy and postpartum period
- High risk women (health risks including epilepsy, insulin dependent diabetes, BMI >35, family history of NTD, high risk ethnic group): at least 3 mo prior to conception until 10-12 wk post conception
- For women ≥50 yr: daily folic acid supplementation for at least 2-3 mo before conception and throughout pregnancy and postpartum period
- High risk women (health risks including epilepsy, insulin dependent diabetes, BMI >35, family history of NTD, high risk ethnic group): at least 3 mo prior to conception until 10-12 wk post conception
- For women ≥50 yr: daily folic acid supplementation for at least 2-3 mo before conception and throughout pregnancy and postpartum period
- High risk women (health risks including epilepsy, insulin dependent diabetes, BMI >35, family history of NTD, high risk ethnic group): at least 3 mo prior to conception until 10-12 wk post conception
- For women ≥50 yr: daily folic acid supplementation for at least 2-3 mo before conception and throughout pregnancy and postpartum period
- High risk women (health risks including epilepsy, insulin dependent diabetes, BMI >35, family history of NTD, high risk ethnic group): at least 3 mo prior to conception until 10-12 wk post conception
- For women ≥50 yr: daily folic acid supplementation for at least 2-3 mo before conception and throughout pregnancy and postpartum period

---

**Prostate-Cancer Mortality at 11 Years of Follow-up**

**NEJM 2011;364:911-920**

**Study:** Updated “ERSPC” study – multicentre randomised trial of screening for prostate cancer using PSA.

**Patients:** 162,388 men, ages 55-69 from 8 different European countries.

**Intervention:** PSA-based screening.

**Main Outcome:** mortality from prostate cancer

**Results:** After median follow up of 11 yr, the RR of death from prostate cancer was 21%. The ARR was 1.07 deaths/1000 men. NNT=1055 – therefore to prevent one death from prostate cancer at 11 yr follow up, 1055 men would need to be screened.

---

**Appropriate Use of Screening and Diagnostic Tests to Foster High-Value, Cost-Conscious Care**

Aims: Improving value of health care, reduce cost, improve patient outcomes

- Suggested principles for providing high-value, cost-conscious care (see article Table 1 for specific examples):

  1. Diagnostic tests should not be performed if the results will not change management.
  2. If the pretest probability of disease is low, the likelihood of a false-positive test result is higher than the likelihood of a true-positive result. False-positive results often lead to further testing, which may be expensive and potentially harmful (e.g. anxiety for patient, inappropriate treatment).
  3. The true cost of a test includes not only the cost of the test itself but also the downstream costs incurred because the test was performed. These include the costs of subsequent testing, treatment, or follow-up.
Colorectal Cancer Screening Guidelines

- recommendations for average risk individuals (asymptomatic, no history of UC, polyps, or CRC):
  - Canadian Association of Gastroenterology (2010):
    - FOBT q1-2yr
    - flexible sigmoidoscopy q10yr
    - flexible sigmoidoscopy + FOBT q5yr
    - for UC patients, colonoscopy q1-2yr after 8 yr of disease

![Diagram of colorectal cancer screening guidelines]

Cervical Cancer Screening

- either conventional Papanicolaou (Pap) smear or liquid based cytology testing
- endocervical and exocervical cell sampling (aim is to sample the transitional zone)
- best identifies squamous cell abnormalities, less reliable for glandular abnormalities
  - false positives 5-10%, false negatives 10-40% (for single test)
  - false negative rate 50% for existing cervical cancer
- cervical cancer screening guidelines differ by Canadian jurisdiction (see The Society of Obstetricians and Gynaecologists of Canada updated guidelines)

- Canadian guidelines:
  - screen all women age ≥25 q3yr
  - women age ≥70: if 3 normal tests in a row and no abnormal tests in last 10 yr, can discontinue screening

- Ontario guidelines:
  - screen all women age ≥21 who are or have ever been sexually active (includes intercourse or digital/oral activity with partner of either gender)
  - if cytology is normal, can screen every 3 yr
  - women age ≥70: if 3 successive negative Pap tests in last 10 yr, can discontinue screening

- pregnant women and women who have sex with women should follow the routine cervical screening regimen
- women who have had a hysterectomy:
  - total: discontinue screening if hysterectomy was for benign disease and no history of cervical dysplasia or HPV infection
  - subtotal: continue screening according to guidelines
- exceptions to guidelines:
  - immunocompromised (transplant, steroids, diethylstilbestrol exposure, HIV)
  - adolescent women
  - previously unscreened patients

Figure 1. Approach to higher risk screening

AAPC = attenuated adenomatous polyposis; FAP = familial adenomatous polyposis; HNPCC = hereditary nonpolyposis colorectal cancer; 1st degree relatives: parents, siblings, children; 2nd degree relatives: grandparents, aunts, uncles; 3rd degree relatives: great grandparents or cousins

Health Promotion and Counselling

- Health promotion is the most effective preventative strategy.
- 40-70% of productive life lost annually is preventable.
- There are several effective ways to promote healthy behavioural change, such as discussions appropriate to a patient's present stage of change.

Motivational Strategies for Behavioural Change

<table>
<thead>
<tr>
<th>Patient's Stage of Change</th>
<th>Physician's Aim</th>
<th>Physician's Plan</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-contemplation</td>
<td>Encourage patient to consider the possibility of change</td>
<td>Raise issue in a sensitive manner</td>
</tr>
<tr>
<td></td>
<td>Assess readiness for change</td>
<td>Offer (not impose) a neutral exchange of information to avoid resistance</td>
</tr>
<tr>
<td></td>
<td>Increase patient’s awareness of the problem and its risks</td>
<td></td>
</tr>
<tr>
<td>Contemplation</td>
<td>Understand patient’s ambivalence and encourage change</td>
<td>Offer opportunity to discuss pros and cons of change using reflective listening</td>
</tr>
<tr>
<td></td>
<td>Build confidence and gain commitment to change</td>
<td></td>
</tr>
<tr>
<td>Preparation</td>
<td>Explore options and choose course most appropriate to patient</td>
<td>Offer realistic options for change and opportunity to discuss inevitable difficulties</td>
</tr>
<tr>
<td></td>
<td>Identify high-risk situations and develop strategies to prevent relapse</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Continue to strengthen confidence and commitment</td>
<td></td>
</tr>
<tr>
<td>Action</td>
<td>Help patients design rewards for success</td>
<td>Offer positive reinforcement and explore ways of coping with obstacles</td>
</tr>
<tr>
<td></td>
<td>Develop strategies to prevent relapse</td>
<td>Encourage self-rewards to positively reinforce change</td>
</tr>
<tr>
<td></td>
<td>Support and reinforce convictions towards long-term change</td>
<td></td>
</tr>
<tr>
<td>Maintenance</td>
<td>Help patient maintain motivation</td>
<td>Discuss progress and signs of impending relapse</td>
</tr>
<tr>
<td></td>
<td>Review identified high-risk situations and strategies for preventing relapse</td>
<td></td>
</tr>
<tr>
<td>Relapse</td>
<td>Help patient view relapse as a learning experience</td>
<td>Offer a non-judgmental discussion about circumstances surrounding relapse and how to avoid relapse in the future</td>
</tr>
<tr>
<td></td>
<td>Provide support appropriate to present level of readiness post-relapse</td>
<td>Reassess patient’s readiness to change</td>
</tr>
</tbody>
</table>

Nutrition

General Population
- Canada's Food Guide is appropriate for individuals age ≥2.
- Counsel on variety, portion size, and plate layout (see Figure 3).

### Obesity

- body mass index (BMI) = weight (kg)/height (m)^2 = weight (lbs)/height (inch)^2 x 703; BMI is a poor predictor of obesity
- waist circumference (WC)
  - should be measured in all adults to assess obesity-related health risks
  - specific cutoff points exist for different ethnic backgrounds (as recommended by the 2006 Canadian Clinical Practice Guidelines on obesity)
  - measurement of waist-hip ratio has no advantage over waist circumference alone

Table 7. Classification of Weight by BMI, Waist Circumference, and Associated Disease Risks in Adults

</table>

### Epidemiology

- 16% (4 million) of people ≥18 yr old are obese, 32% (8 million) are overweight in Canada, according to StatsCan (2007)
- obesity rate in people of aboriginal origin is 1.6 times higher than the national average
- proportion of children aged 6-11 who are overweight has more than doubled in the last 25 yr; percentage of overweight adolescents has tripled
- overweight and obesity rates in children are directly proportional to screen time (see Exercise, FM10)
- only 10-15% of population consume <30% fat daily
- obese persons generally consume more energy-dense food which tends to be highly processed, micronutrient poor, and high in fats, sugars, or starch

### Adverse Medical Consequences of Obesity

- Type 2 DM
- CAD
- Stroke
- HTN
- Gallbladder disease
- Non-alcoholic steatohepatitis
- Complications of pregnancy
- Dyslipidemia
- Osteoarthritis
- Sleep apnea
- Certain cancers
- CHF
- Low back pain
- Increased total mortality

### Losing Weight

- Aim for caloric intake 500-1000 kcal/d less than total daily energy expenditure (TDEE)
- Results in 1-2 lb (0.5-1 kg) weight loss per wk
- Achieved by combination of increased activity and/or decreased caloric intake

### Low BMI is associated with:

- Osteoporosis
- Eating disorders
- Under-nutrition
- Pregnancy complications

- Burning Fat
  - 3500 kcal of energy are used for every pound of human fat burned during activity.

- Low BMI is associated with:
  - Osteoporosis
  - Eating disorders
  - Undernutrition
  - Complications of pregnancy
Dyslipidemia

- see Endocrinology, E2
- defined as abnormal elevation of plasma cholesterol or triglyceride levels
- increased risk associated with obesity, DM, alcohol use

Assessment
- measure fasting serum TC, LDL-C, HDL-C, and TG
- screen with full fasting lipid profile q1-3yr in males over age 40, females over age 50 or who are menopausal, or any adults with additional CAD risk factors
- assess for presence of other CAD risk factors
- screen for secondary causes: hypothyroidism, chronic kidney disease, DM, nephrotic syndrome, liver disease
- risk category
  - estimate using the model for 10-yr CAD risk developed from the Framingham data (Framingham Risk Score – FRS)
  - FRS calculated based on the following factors: gender, age, HDL-C, total cholesterol, sBP, smoking, diabetes
    - to be completed for men age 40-75, and women age 50-75 q3-5yr
• cardiovascular age calculated as patient’s age ± the difference between his or her estimated remaining life expectancy
  used to increase adherence to therapy and reaffirm positive effect of following therapy
• primary target of therapy is LDL-C levels; the alternate primary targets are apolipoprotein B (apo B) and non-HDL-C (not used widely yet) (see Table 8)
• optional secondary targets once LDL-C/apo B is at target include TCHDL-C ratio, apo B:apo AI ratio, hs-CRP (used more for risk stratification of CAD), non-HDL-C and serum TG levels
• emerging risk factors (from Framingham group)
  ▪ lipoprotein a
  ▪ metabolic syndrome
  ▪ genetic risk
  ▪ hormone replacement therapy
  ▪ infectious agents

Table 8. Target Lipid Values for Primary Prevention of CAD (2012 Canadian Cholesterol Guidelines)

<table>
<thead>
<tr>
<th>Risk Category</th>
<th>Initiate Treatment if:</th>
<th>Primary Targets</th>
<th>Alternate</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Consider treatment in all patients</td>
<td>LDL-C &lt; 2 mmol/L or ≥50% decrease in LDL-C</td>
<td>apo B &lt; 0.80 g/L or ≤2.6mmol/L</td>
</tr>
<tr>
<td>Moderate (FRS 10-19%)</td>
<td>LDL-C ≥ 3.5 mmol/L</td>
<td>apo B ≥ 1.2 g/L or ≤50% decrease in LDL-C</td>
<td>non-HDL-C ≥ 4 mmol/L</td>
</tr>
<tr>
<td>Low (FRS ≤ 10%)</td>
<td>LDL-C ≥ 5.0 mmol/L</td>
<td>Familial hypercholesterolemia</td>
<td>≥50% decrease in LDL-C</td>
</tr>
</tbody>
</table>

Management
• intensity and type of treatment is guided by “risk category” assigned
  1. health behaviours (can decrease LDL-C by up to 10%)
     ▪ smoking cessation: probably the most important for preventing CAD
     ▪ dietary modification: reduce saturated fats, refined sugars, alcohol; increase fruits, vegetables and fibres
     ▪ physical activity: at least 150 min of moderate to vigorous intensity aerobic exercise per week
     ▪ employ consistent lifestyle modifications for at least 3 mo before considering drug therapy; high risk patient should start treatment immediately with concurrent health behaviour interventions
  2. pharmacologic therapy (can decrease LDL-C by up to 40%)
     ▪ for a comparison of dyslipidemia medications, see Endocrinology, E5
     ▪ statins (HMG-CoA reductase inhibitors)
       ▪ currently recommended as 1st line monotherapy following unsuccessful lifestyle modifications
       ▪ risks: myopathy and hepatotoxicity – must follow LFTs q6-12mo
     ▪ other agents: bile acid sequestrants, nicotinic acid, fibrates, psyllium, cholesterol absorption inhibitors (e.g. ezetimibe)
     ▪ after initiating drug therapy
       ▪ monitor ALT, AST, CK at baseline then 6 wk later for signs of transaminitis or myositis; tolerate rise in CK up to 10 times upper limit of normal (2-3 times upper limit of normal if symptomatic), or serum creatinine of ≤25%; repeat ALT, AST and CK with lipid bloodwork
       ▪ fasting lipids should be measured at 3 mo
       ▪ if adequate response is achieved, evaluate fasting lipids q6-12mo
     ▪ isolated hypertriglyceridemia (does not increase your cardiovascular risk!)
       ▪ normal HDL-C and TC, elevated TG
       ▪ mild ≥2.2 mmol/L (≥200 mg/dL); marked ≥5.6 mmol/L (≥500 mg/dL)
       ▪ principal therapy is lifestyle modification
       ▪ weight loss, exercise, avoidance of smoking and alcohol, effective blood glucose control in diabetics, increased omega-3 fatty acid intake
     ▪ drug therapy
       ▪ nicotinic acid
       ▪ fibrates

Clinical Definition of Metabolic Syndrome
• Central obesity:
  Men – waist circumference ≥94 cm
  Women – waist circumference ≥80 cm
• Plus any TWD of the following four factors:

<table>
<thead>
<tr>
<th>Risk Factor</th>

To calculate Framingham Risk Score, go to http://www.framinghamheartstudy.org/risk-functions/cardiovascular-disease-10-year-risk.php#

With use caution when prescribing combined statin and fibrate therapy as there has been concern regarding the safety of certain combinations.

Statin-Related Adverse Events: A Meta-analysis
Clin Ther 2008;29:26-35
Study: Meta-analysis of 18 RCTs (N=71,108) focused on adverse effects of statins.
Patients: Those taking statin monotherapy for primary or secondary prevention of CVD.
Intervention: Statin vs. placebo.
Main outcome: Adverse events (AE) including elevated liver enzymes or myopathy (myalgias, elevated CK, rhabdomyolysis).
Results: Statin therapy increased the risk of any AE by 39% (OR = 1.39, 95% CI, 1.09-1.80, P = 0.008) compared with placebo. Treating 1000 patients with a statin would cause 5 AE. Serious events (CK >10 times the upper limit of normal or rhabdomyolysis) are infrequent (NNH = 4300) and rhabdomyolysis, although serious, is rare (NNH = 4300).
Conclusion: Statin therapy was associated with greater odds of AEs compared with placebo but with substantial clinical benefit. Similar rates of serious AEs were observed between statin and placebo.

The Benefits of Statins in People without Established Cardiovascular Disease but with Cardiovascular Risk Factors: Meta-Analysis of Randomized Controlled Trials
Study: Meta-analysis of 10 RCTs.
Population: 70,388 participants (minimum of 80% without established cardiovascular (CV) disease).
Intervention: Statins, placebo, active control, usual care.
Main outcome: All-cause mortality. Other outcomes: major coronary events, major cerebrovascular events.
Results: Statin use significantly reduced the incidence of all-cause mortality (OR 0.88; 95% CI 0.81-0.96), major coronary events (OR 0.70; 95% CI 0.63-0.81) and major cerebrovascular events (OR 0.81; 95% CI 0.71-0.93).
Conclusion: Statins largely reduce the risk of major CV events and improve survival in patients with CV risk factors without established CV disease.

To ronto Notes 2014

Use with caution when prescribing combined statin and fibrate therapy as there has been concern regarding the safety of certain combinations.

The Benefits of Statins in People without Established Cardiovascular Disease but with Cardiovascular Risk Factors: Meta-Analysis of Randomized Controlled Trials
Study: Meta-analysis of 10 RCTs.
Population: 70,388 participants (minimum of 80% without established cardiovascular (CV) disease).
Intervention: Statins, placebo, active control, usual care.
Main outcome: All-cause mortality. Other outcomes: major coronary events, major cerebrovascular events.
Results: Statin use significantly reduced the incidence of all-cause mortality (OR 0.88; 95% CI 0.81-0.96), major coronary events (OR 0.70; 95% CI 0.63-0.81) and major cerebrovascular events (OR 0.81; 95% CI 0.71-0.93).
Conclusion: Statins largely reduce the risk of major CV events and improve survival in patients with CV risk factors without established CV disease.
Exercise

Epidemiology
- 25% of the population exercises regularly, 50% occasionally, 25% are sedentary
- screen time (time spent watching TV/movies, playing video games, or using the computer) has been increasing steadily in the last several yr, while time spent being physically active has been decreasing
- current recommendation from international pediatric societies is that children (>2 yr old) should limit their screen time to less than 2 h/d

Management
- assess current level of fitness, motivation and access to exercise
- encourage warm up and cool down periods to allow transition between rest and activity and to avoid injuries
- exercise with caution for patients with CAD, diabetes (risk of hypoglycemia), exercise-induced asthma
- patients with known CAD should have cardiac assessment prior to commencing exercise
- Canadian Physical Activity Guidelines for adults age 18-64 (ParticipACTION)
  - ≥150 min of moderate- to vigorous-intensity aerobic physical activity per wk, in bouts of ≥10 min
  - moderate-intensity: brisk walking, bike riding
  - vigorous-intensity: jogging, cross-country skiing
- muscle and bone strengthening activities using major muscle groups, ≥2 d/wk
- benefits of exercise
  - reduces risk of premature death, heart disease, stroke, HTN, certain types of cancer, type 2 diabetes, osteoporosis, overweight/obesity
  - leads to improved fitness, strength, and mental health (morale and self-esteem)

Smoking Cessation

Epidemiology
- smoking is the single most preventable cause of premature illness and death
- 70% of smokers see a physician each year
- 2008 Canadian data from the Canadian Tobacco Use Monitoring Survey (CTUMS) on population age 15 or older
  - 18% are current smokers (lowest since 1965)
  - highest prevalence in age group 20-24 (28%)
  - 15% of youth age 15-19 smoke (decreased from 25% in 2000): more males smoke than females; number of cigarettes consumed per day also decreasing

Management
- general approach
  - identify tobacco users; elicit smoking habits, previous quit attempts and results
  - every smoker should be offered treatment
  - make patient aware of withdrawal symptoms
    - low mood, insomnia, irritability, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite
  - ≥4 counselling sessions >10 min each with 6-12 mo follow-up yields better results
  - 14% abstinent with counselling vs. 10% without counselling
  - approach depends on patient's stage of change (see Motivational Strategies for Behavioural Change, FM5)
  - willing to quit
    - follow the 5 As (see sidebar)
    - provision of social support, community resources
    - pregnant patients: advise to quit first without pharmacotherapy. Nicotine replacement therapy (NRT) should be made available to pregnant women who are unable to quit using non-pharmacologic methods; nicotine patches are strongly encouraged. Use bupropion (no evidence of fetal or reproductive harm) only if benefits > risks; consult Motherisk. Varenicline has not been studied in pregnancy and should not be used in pregnant women
  - pharmacologic therapy
    - 19.7% abstinent at 12 mo with NRT vs. 11.5% for placebo
    - no difference in achieving abstinence for different forms of NRT
    - reduces cravings and withdrawal symptoms without other harmful substances that are contained in cigarettes
    - use with caution: immediate post-MI, serious/worsening angina, serious arrhythmia

Physician Advice for Smoking Cessation
Cochrane DB Syst Rev 2008;2:CD000165
This systematic review of 17 trials compared brief advice by the physician versus no advice.
Reviewers' conclusions: Simple advice can increase cessation rates by 1-3%. More intensive advice and providing follow-up support may further increase the quit rates.

Assist Patient in Developing Quit Plan
STAR
- Set quit date
- Tell family and friends (for support)
- Anticipate challenges (e.g. withdrawal)
- Remove tobacco-related products (e.g. ashtrays/lighters)

The 5 As for Patients Willing to Quit
Ask if patient smokes
Advise patient to quit
Assess willingness to quit
Assist in quit attempt
Arrange follow-up

</table>

• unwilling to quit
  • motivational intervention (5 Rs) (see sidebar):
    1. Relevance to patient
      • relevant to patient’s disease status or risk, family or social situation (e.g. having children in the home), health concerns, age, gender
    2. Risks of smoking
      • short-term: SOB, asthma exacerbation, impotence, infertility, pregnancy complications, heartburn, URTI
      • long-term: MI, stroke, COPD, lung CA, other cancers
    3. Environmental: higher risk in spouse/children for lung CA, SIDS, asthma, respiratory infections
  3. Rewards: benefits
    • improved health, save money, food tastes better, good example to children
  4. Roadblocks: obstacles
    • fear of withdrawal, weight gain, failure, lack of support
  5. Repetition
    • reassure unsuccessful patients that most people try many times before successfully quitting (average number of attempts before success is 7)
• recent quitter
  ▪ highest relapse rate within 3 mo of quitting
  ▪ minimal practice: congratulate on success, encourage ongoing abstinence, review benefits and problems
  ▪ prescriptive interventions: address problem of weight gain, negative mood, withdrawal, lack of support

## Alcohol

• see Psychiatry, PS22

### Definition

• diagnostic categories occur along a continuum (see Figure 5)

### Epidemiology

• 10-15% of patients in family practice are problem drinkers
• 20-50% of hospital admissions, 10% of premature deaths, 30% of suicides, and 50% of fatal traffic accidents in Canada are alcohol-related
• more likely to miss diagnosis in women, elderly, patients with high socioeconomic status

### Assessment

• screen for alcohol dependence with CAGE questionnaire (see sidebar)
  ▪ if CAGE positive, explore with further questions for alcohol abuse/dependence
• assess drinking profile
  ▪ setting, time, place, occasion, with whom
  ▪ impact on: family, work, social
  ▪ quantity-frequency history
    ▪ how many drinks per day?
    ▪ how many days per week?
    ▪ maximum number of drinks on any one day in the past month?
• if identified positive for alcohol problem
  ▪ screen for other drug use
  ▪ identify medical/psychiatric complications
  ▪ ask about drinking and driving
  ▪ ask about past recovery attempts and current readiness for change

### Investigations

• GGT and MCV for baseline and follow-up monitoring
• AST, ALT (usually AST:ALT approaches 2:1 in an alcoholic)
• CBC (anemia, thrombocytopenia), INR (decreased clotting factor production by liver)

### Management

• intervention should be consistent with patient's motivation for change
• regular follow-up is crucial
• 10% of patients in alcohol withdrawal will have seizures or delirium tremens
• Alcoholics Anonymous/12-steps program
• outpatient/day programs for those with chronic, resistant problems
• family treatment (Al-Anon, Alateen, screen for spouse/child abuse)
• in-patient program if
  ▪ dangerous or highly unstable home environment
  ▪ severe medical/psychiatric problem
  ▪ addiction to drug that may require in-patient detoxification
  ▪ refractory to other treatment programs
• pharmacologic
  ▪ diazepam for withdrawal
  ▪ disulfiram (Antabuse™): impairs metabolism of alcohol by blocking conversion of acetaldehyde to acetic acid, leading to flushing, headache, nausea/vomiting, hypotension if alcohol is ingested (available in U.S., but no longer available in Canada)
  ▪ naltrexone: competitive opioid antagonist that reduces cravings and pleasurable effects of drinking
  ▪ may trigger withdrawal in opioid-dependent patients

### Prognosis

• relapse is common and should not be viewed as failure
• monitor regularly for signs of relapse
• 25-30% of abusers exhibit spontaneous improvement over 1 yr
• 60-70% of individuals with jobs and families have an improved quality of life 1 yr post-treatment

### Abstinence

#### Low Risk Drinking

<2 drinks/d
<9 drinks/wk for women
<14 drinks/wk for men

#### At Risk Drinking

Consumption above low-risk level but no alcohol-related physical or social problems

### Alcohol Abuse

Physical or social problems
Continued use despite consequences
Inability to fulfill life roles
Legal problems
No evidence of dependence

### Alcohol Dependence

#### Figure 5. Continuum of alcohol use

### Standard Drink Equivalents

- One standard drink = 14 g of pure alcohol
- Beer (5% alcohol) = 12 oz
- Wine (12-17% alcohol) = 5 oz
- Fortified wine = 3 oz
- Hard liquor (80 proof) = 1.5 oz

### CAGE Questionnaire

- C Have you ever felt the need to CUT down on your drinking?
- A Have you ever felt ANNOYED at criticism of your drinking?
- G Have you ever felt GUILTY about your drinking?
- E Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover? (EYE OPENER)

2 or more for men or ≥1 for women suggests possibility of problem drinking (sensitivity 85%, specificity 89%)

### Alcohol Metabolized per Hour

- Alcohol metabolism is constant (zero-order kinetics) regardless of blood alcohol level (BAL)
- Average metabolism ranges between 13.25 mg/dL blood/h or 100-200 mg/kg/h
- Equivalent to metabolizing 0.5-1 standard drink per hour or BAL decrease of 0.01% per hour
- Metabolism more rapid in chronic alcoholics

### Some Adverse Medical Consequences of Problem Drinking

- GI: gastritis, dyspepsia, pancreatitis, liver disease, bleeds, diarrhea, oral/esophageal cancer
- Cardiac: hypertension, alcoholic cardiomyopathy
- Neurologic: Wernicke-Korsakoff syndrome, peripheral neuropathy
- Hematologic: anemia, coagulopathies
- Other: trauma, insomnia, family violence, anxiety/depression, social/family dysfunction, sexual dysfunction, fetal damage
Common Presenting Problems

Abdominal Pain

- see Gastroenterology, G4 and General Surgery, GS4

Epidemiology
- 20% of individuals have experienced abdominal pain within the last 6-12 mo
- 90% resolve in 2-3 wk
- only 10% are referred to specialists, of those <10% admitted to hospital

Etiology
- most common diagnosis is “nonspecific abdominal pain,” which has no identifiable cause and is usually self-limited
- GI disorders (e.g. PUD, pancreatitis, IBD, appendicitis, gastroenteritis, IBS, diverticular disease, biliary tract disease)
- urinary tract disorders (e.g. UTI, renal calculi)
- gynecological disorders (e.g. PID, ectopic pregnancy, endometriosis)
- cardiovascular disorders (e.g. CAD, AAA, ischemic bowel)
- other: toxic ingestion, foreign body, psychogenic

Pathophysiology
- type of pain
  - somatic pain: sharp, localized pain
  - visceral pain: dull, generalized pain
- location of pain
  - epigastric (foregut): distal esophagus, stomach, proximal duodenum, biliary tree, pancreas, liver
  - periumbilical (midgut): distal duodenum to proximal 2/3 of transverse colon
  - hypogastric (hindgut): distal 1/3 of transverse colon to rectosigmoid region

Investigations
- guided by findings on history and physical
- possible bloodwork: CBC, electrolytes, BUN, Cr, amylase, lipase, AST, ALT, ALP, bilirubin, glucose, INR/PTT, tox screen, β-hCG
- imaging
  - CXR (for free air under the diaphragm) in setting of perforation in surgical abdomen
  - abdominal x-ray, KUB (consider: gas pattern, free air, kidney stones, constipation)
  - ultrasound (gallbladder disease, gynecological problems, liver disease, pancreatitis, diverticular disease, appendicitis)
  - CT scan (AAA, appendicitis)
- other tests
  - urinalysis
  - endoscopy (for peptic ulcers, gastritis, tumours, etc.)
  - H. pylori testing (urea breath test, serology, biopsy)

Allergic Rhinitis

- see Otolaryngology, OT23

Definition
- inflammation of the nasal mucosa that is triggered by an allergic reaction
- classification:
  - seasonal
    - symptoms during a specific time of the year
    - common allergens: trees, grass and weed pollens, airborne moulds
  - perennial
    - symptoms throughout the year with variation in severity
    - common allergens: dust mites, animal dander, moulds

Etiology
- increased IgE levels to certain allergens → excessive degranulation of mast cells → release of inflammatory mediators (e.g. histamine) and cytokines → local inflammatory reaction
Epidemiology
- affects approximately 40% of children and 20-30% of adults
- prevalence has increased in developed countries, particularly in the past two decades
- associated with asthma, sinusitis, and otitis media

Assessment
- identify allergens
- take an environmental/occupational history
- ask about related conditions (e.g. atopic dermatitis, asthma, sinusitis, and family history)

Management
- conservative
  - minimize exposure to allergens
  - most important aspect of management, often sufficient (may take months)
  - maintain hygiene, saline nasal rinses
- pharmacologic agents
  - oral antihistamines – first line therapy for mild symptoms
    - e.g. cetirizine (Reactine®), fexofenadine (Allegra®), loratadine (Claritin®)
  - intranasal corticosteroids for moderate/severe or persistent symptoms (>1 mo of consistent use to see results)
  - intranasal decongestants (use must be limited to <5 d to avoid rhinitis medicamentosa)
- allergy skin testing
  - for patients with chronic rhinitis
  - symptoms not controlled by allergen avoidance, pharmacological therapy
  - may identify allergens to include in immunotherapy treatment
- immunotherapy (allergy shots)
  - reserved for severe cases unresponsive to pharmacologic agents
  - consists of periodic (usually weekly) subcutaneous injections of custom prepared solutions of one or more antigens to which the patient is allergic

Amenorrhea
- see Gynecology, G12

Definition and Etiology
- classified as primary or secondary
  - primary
    - absence of menstruation by age 14 in women without secondary sexual characteristics or absence of menstruation by age 16 in women with secondary sexual characteristics
    - causes: Turner's syndrome, constitutional delay of growth and puberty, Kallmann syndrome, androgen insensitivity syndrome, Müllerian agenesis, imperforate hymen, transverse vaginal septum, + causes of secondary amenorrhea
  - secondary
    - absence of menstruation for 3 mo in women with previously normal menstruation, or absence of menstruation for 9 mo in women with previous oligomenorrhea
    - causes: pregnancy, hypothyroidism, hyperprolactinemia, medications, premature ovarian failure, anorexia or bulimia nervosa, CNS tumour, chronic illness, PCOS

Assessment
- history
  - menarche and menstrual history, sexual activity, exercise, weight loss, current or previous chronic illness, prescription/illicit drug use, previous CNS chemotherapy or radiation, previous pelvic radiation, psychosocial stressors
  - family history: of genetic defects, infertility, menarche and menstrual history, pubertal history
- physical
  - growth chart, BMI, Tanner staging, dysmorphic features (e.g. webbed neck, short stature), signs of Cushing's disease, thyroid exam, hirsutism or acne, pubic hair pattern, imperforate hymen, absent uterus

Investigations
- based on clinical picture
- consider β-hCG, prolactin, TSH, progesterone challenge test, FSH and LH levels, pelvic ultrasound, MRI brain, karyotype
Anxiety

- see Psychiatry, PS13

Epidemiology
- 25-30% of patients in primary care settings have psychiatric disorders
- many are undiagnosed or untreated; hence the need for good screening
- high rate of coexistence of anxiety disorders and depression

Screening
- screening questions:
  - Do you tend to be an anxious or nervous person?
  - Have you felt unusually worried about things recently?
  - Has this worrying affected your life? How?
- if positive response, follow up with symptom-specific questions (see Figure 6)

Assessment
- associated symptoms
- risk factors
  - family history of anxiety or depression, past history of anxiety, stressful life event, social isolation, female gender, co-morbid psychiatric diagnosis (e.g. depression)
- assess substance abuse, co-morbid depression, suicidal ideation/self-harm
- to differentiate anxiety disorders, consider symptoms and their duration (see Figure 6)

Differential Diagnosis of Anxiety Disorders (see Figure 6)
- Panic disorder
- GAD
- PTSD
- OCD
- Specific phobia
- Separation anxiety (children)
- Other: GMC, mood disorder, psychotic disorder

Management
- patient education: emphasize prevalence, good recovery rate of anxiety conditions
- lifestyle advice: decrease caffeine and alcohol intake, exercise, relaxation techniques, mindfulness strategies
- self-help materials, community resources (e.g. support groups)
- cognitive behavioural therapy: cognitive interventions, exposure therapy, etc.
- for pharmacotherapy, see Psychiatry, PS48

Symptoms of Anxiety
Are the symptoms predominantly...

In the form of panic with physical (autonomic) symptoms?
- Do the panic attacks come...
  - With a specific situation
  - “Out of the blue”
- Is patient avoiding situation?
  - Yes
  - No
- Patient afraid of another attack and its implications?
  - Yes
  - No

Secondary to a specific experienced trauma?
- Excessive worry and apprehension about common concerns?
- Are the thoughts intrusive, inappropriate and distressing?
- Are they accompanied by a repetitive behaviour meant to neutralize the anxiety?
- Excessive worry and apprehension about social situations?

ACUTE STRESS REACTION
- PTSD

ADJUSTMENT DISORDER
- GAD

PANIC DISORDER

SPECIFIC PHOobia

SOCIAL PHOobia

PANIC DISORDER WITH AGORAPHOBia

Figure 6. Differentiating anxiety disorders

Symptoms of GAD
AND I C REST
Anxious, nervous, or worried
- No control over the worry
- Duration >6 mo
- Irritability
- Concentration impairment
- Restlessness
- Energy decreased
- Sleep impairment
- Tension in muscles

Can Fam Physician 2005;51:1340-1342
Asthma/COPD

- see Respirology, R6

Definition
- asthma
  - chronic but reversible airway inflammation characterized by periodic attacks of wheezing, shortness of breath, chest tightness, and coughing
  - airways hyper-responsive to triggers/antigens leading to acute obstructive symptoms by bronchoconstriction, mucous plugs and increased inflammation
  - cannot be diagnosed at first presentation; called reactive airway disease until recurrent presentations
  - pulmonary function tests (PFTs) can be done from age 6 or when child able to follow instructions to do PFTs
  - peak flow meters are useful in the office and at home for monitoring
- chronic obstructive pulmonary disease (COPD)
  - a group of chronic, progressive, expiratory lung diseases characterized by limited airflow with variable degrees of air sac enlargement and lung tissue destruction
  - emphysema and chronic bronchitis are the most common forms of COPD

Table 12. Differentiating COPD from Asthma

<table>
<thead>

</table>
| **Management** | **Mild**
  - Step 1: SABA pm (salbutamol) or LAAC (i.e. tiotropium)
  - Step 2: SABA pm + LAAC (i.e. salbutamol) or LABA (e.g. salmeterol)
  - **Moderate**
  - Step 3: SABA pm + LAAC + low-dose combined ICS/LABA; consider inhaled vs. oral steroids
  - **Severe**
  - Step 4: ± theophylline | Ongoing patient education, and environmental control SABA taken pm as rescue medication + maintenance meds |
  | **Maintenance medications:** | **Step 1:** Low-dose ICS
  | | **Step 2:** Medium/high-dose ICS or low-dose ICS plus either LABA, LT modifier, or long-acting theophylline
  | | **Step 3:** Medium/high-dose ICS plus either LABA, LT modifier, or long-acting theophylline
  | | **Step 4:** As above plus immunotherapy ± oral glucocorticosteroids + pneumococcal vaccination, annual influenza immunization |

β₂-agonists
- Salbutamol – Ventolin® light blue/navy
- Salmeterol – Seretide® teal/light teal
- Terbutaline – Bricanyl® blue/white

ICS
- Fluticasone – Flonvert® orange/peach
- Budesonide – Pulmicort® white/brown

Combined long-acting β₂-agonist + ICS
- Fluticasone/Salmeterol – Advair® purple discus
- Budesonide/Formoterol – Symbicort® red/white
- Ipratropium/Albuterol – Combivent® clear/orange

Anticholinergics
- Ipratropium – Atrovent® clear/green
- Tiotropium – Spiriva® white/turquoise

More about Inhalers:
- Aerosols (puffers=MDIs, MDI + spacer)
- MDIs should be used with spacers to:
  - Reduce side effects
  - Improve amount inhaled
  - Increase efficiency of use
- Dry powder inhaler (discus, turbuhaler and diskhaler), they require deep and fast breathing (may not be ideal for children)
- Nebulizers can be used to convert liquid medications into a fine mist: recommended for use if contraindications to MDIs

Differential Diagnosis of Wheezing
- Allergies, anaphylaxis
- Asthma, reactive airway disease
- Gastroesophageal reflux disease
- Infections (bronchitis, pneumonia)
- Obstructive Sleep Apnea
- COPD
- Less common: congestive heart disease, foreign body, malignancy, cystic fibrosis, vocal cord dysfunction

When prescribing salbutamol, watch out for signs of hypokalemia: lethargy, irritability, paresthesias, myalgias, weakness, palpitations, nausea, vomiting, polyuria.
Benign Prostatic Hyperplasia (BPH)

- see Urology, U8

Definition
- hyperplasia of the stroma and epithelium in the periurethral transition zone

History and Physical
- include current/past health, surgeries, trauma, current and OTC meds
- specific urinary symptoms (see Table 13)
- physical exam must include DRE for size, symmetry, nodularity, and texture of prostate (prostate is symmetrically enlarged, smooth and rubbery in BPH)

Investigations
- urinalysis to exclude UTI and for microscopic hematuria (common sign)
- serum PSA: protein produced by prostatic tissue, see Urology, U25
  - values:
    - <4.0 ng/mL: normal, but must take into account patient’s age and velocity of PSA increase
    - 4-10 ng/mL: consider measuring free/total PSA
    - >10 ng/mL: high likelihood of prostate pathology
- PSA testing is inappropriate in men with a life expectancy less than 10 yr or patients with prostatitis, UTI
- increased PSA in a younger man is more often due to cancer than other causes
- abnormal DRE or PSA should trigger further assessment
- discuss test with men at increased risk of prostate cancer (FHx, African ancestry) or who are concerned about development of prostate cancer
- decision to test PSA in an asymptomatic man should involve discussion about the risks and possible benefits
- other tests:
  - Cr, BUN
  - post-void residual volume by ultrasound
  - urodynamic studies, renal ultrasound
  - patient voiding diary
- tests NOT recommended as part of routine initial evaluation include:
  - cystoscopy
  - cytology
  - prostate ultrasound or biopsy
  - IVP

Table 13. Symptoms and Complications of BPH

<table>
<thead>

<tr>
<td>Overflow incontinence</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Nocturia</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Management
- referral to urologist if moderate/severe symptoms
- conservative: for patients with mild symptoms or moderate/severe symptoms considered by the patient to be non-bothersome
  - fluid restriction (avoid alcohol and caffeine)
  - avoidance/monitoring of certain medications (e.g. antihistamines, diuretics, antidepressants, decongestants)
  - pelvic floor/Kegel exercises
  - bladder retraining (scheduled voiding)
- pharmacological: for moderate/severe symptoms
  - α-receptor antagonists [e.g. terazosin (Hytrin®), doxazosin (Cardura®), tamsulosin (Flomax®), alfuzosin (Xatral®)]
    - relaxation of smooth muscle around the prostate and bladder neck
  - 5α-reductase inhibitor [e.g. finasteride (Proscar®)]
    - only for patients with demonstrated prostatic enlargement due to BPH
    - inhibits enzyme responsible for conversion of testosterone into dihydrotestosterone (DHT) thus reducing growth of prostate

Differential Diagnosis
- Prostate cancer
- Urethral obstruction
- Bladder neck obstruction
- Neurogenic bladder
- Cystitis
- Prostatitis

Prostate-Cancer Mortality at 11 Years of Follow-up
- NEJM 2012;366:981-90
- Study: Updated “ERSPC” study – multicentre randomized trial of screening for prostate cancer using PSA.
- Patients: 162,388 men, age 55-69 from 8 different European countries.
- Intervention: PSA-based screening.
- Main Outcome: Mortality from prostate cancer.
- Results: In screening group, ARR = 21%, ARR = 1.07 deaths/1000 men, NNT = 1055 – therefore to prevent one death from prostate cancer, 1055 men would need to be screened.
phytotherapy (e.g. saw palmetto berry extract, *Pygeum africanum*)
- more studies required before this can be recommended as standard therapy
- considered safe
- surgical:
  - TURP (transurethral resection of the prostate), TUIP (transurethral incision of the prostate, for prostates <30 g)
  - absolute indications: failed medical therapy, intractable urinary retention, benign prostatic obstruction leading to renal insufficiency
  - complications: impotence, incontinence, ejaculatory difficulties (retrograde ejaculation), decreased libido

### Bronchitis (Acute)

**Definition**
- acute infection of the tracheobronchial tree causing inflammation leading to bronchial edema and mucus formation

**Epidemiology**
- 5th most common diagnosis in family medicine, most common is URTI

**Etiology**
- 80% viral: rhinovirus, coronavirus, adenovirus, influenza, parainfluenza, respiratory syncytial virus (RSV)
- 20% bacterial: *M. pneumoniae, C. pneumoniae, S. pneumoniae*

**Investigations**
- acute bronchitis is typically a clinical diagnosis
- sputum culture/Gram stain is not very informative
- CXR if suspect pneumonia (cough >3 wk, abnormal vital signs, localized chest findings) or CHF
- pulmonary function tests with methacholine challenge if suspect asthma

**Management**
- primary prevention: frequent hand washing, smoking cessation, avoid irritant exposure
- symptomatic relief: rest, fluids (3-4 L/d when febrile), humidity, analgesics and antitussives as required
- bronchodilators may offer improvement of symptoms (e.g. salbutamol)
- current literature does not support routine antibiotic treatment for the management of acute bronchitis because it is most likely to be caused by a viral infection
  - antibiotics may be useful if elderly, comorbidities, suspected pneumonia, or if the patient is toxic (refer to *Antimicrobial Quick Reference, FM53*)
  - antibiotics in children show no benefit

**Chest Pain**

- see *Cardiology and Cardiovascular Surgery, C4* and *Emergency Medicine, ER21*

**Differential Diagnosis**

*Emergent

**Investigations**
- ECG, CXR, and others if indicated (cardiac enzymes, D-dimers, liver function tests (LFTs), etc.)
- refer to ER if suspect serious etiology (e.g. aortic dissection, MI)

**Management of Common Causes of Chest Pain**
- angina/ischemic heart disease
  - nitroglycerin (NTG): wait 5 min between sprays and if no effect after 3 sprays, send to ER
- myocardial infarction
  - ASA (162-325 mg, chewed), clopidogrel (Plavix*), enoxaparin, morphine, oxygen, NTG
Reperfusion therapy with tissue plasminogen activator (tPA) or streptokinase (SK) if within 6 h (Note: can only use SK once in lifetime) or percutaneous intervention (cath lab)

- start β-blocker (e.g. metoprolol starting dose 12.5 mg PO OD and gradually increase dose, titrate to the HR rate goal of 60 bpm)

- endocarditis: antibiotic choice is based on whether patient has a native or prosthetic heart valve as well as culture and sensitivity results

- GERD: antacids, 

- costochondritis: NSAIDs

**Stable Ischemic Heart Disease**

- Life-style modification (address diet, alcohol, smoking, exercise)
- Manage concomitant disorders (e.g. hypertension, diabetes, hyperthyroidism, anemia)
- Anti-platelet therapy for all patients (ASA 81 mg PO OD unless contraindicated or failed)
- β-blocker for all post-MI patients or those with heart failure
- ACE inhibitor for patients age >55 or with any coincident indication
- Statin therapy for patients with coronary disease

- If symptoms persist
  - Start a β-blocker (if not already using it)/switch to β-1 selective blocker
  - Sublingual nitrate for prophylaxis and acute symptom relief

- If symptoms persist
  - Add long-acting (oral or transdermal) nitrate ± calcium channel blocker

- If symptoms persist
  - Assess suitability for coronary artery revascularization

**Common Cold (Acute Rhinitis)**

**Definition**
- viral URTI with inflammation

**Epidemiology**
- most common diagnosis in family medicine, peaks in winter months
- incidence: adults = 2-4/yr, children = 6-10/yr
- organisms
  - mainly rhinoviruses (30-35% of all colds)
  - others: coronavirus, adenovirus, RSV, influenza, parainfluenza, coxsackie virus
- incubation: 1-5 d
- transmission: person-person contact via secretions on skin/objects and by aerosol droplets

**Risk Factors**
- psychological stress, excessive fatigue, allergic nasopharyngeal disorders, smoking, sick contacts

**Clinical Features**
- symptoms
  - local: nasal congestion, clear to mucopurulent secretions, sneezing, sore throat, conjunctivitis, cough
  - general: malaise, headache, myalgias, mild fever
- signs
  - boggy and erythematous nasal/oropharyngeal mucosa, enlarged lymph nodes
  - normal chest exam
- complications
  - secondary bacterial infection: otitis media, sinusitis, bronchitis, pneumonia
  - asthma/COPD exacerbation

**Differential Diagnosis**
- allergic rhinitis, pharyngitis, influenza, laryngitis, croup, sinusitis, bacterial infections

**High-Risk Symptoms and Signs of Chest Pain include:**
- Severe pain
- Pain for <20 min
- New onset pain at rest
- Severe SOB
- Loss of consciousness
- Hypotension
- Tachycardia
- Bradycardia
- Cyanosis

**Zinc for the Treatment of the Common Cold: A Systematic Review and Meta-Analysis of Randomized Controlled Trials**

- Study: Meta-analysis of 17 randomized control trials with a total of 2127 participants.
- Patients: All populations.
- Intervention: Oral zinc vs. placebo or no treatment.
- Results: Patients receiving zinc had a shorter duration of cold symptoms compared with those given placebo (mean difference -1.85 d). Zinc shortened the duration of symptoms in adults but no significant difference was seen in children. Adverse event such as nausea were more common in the zinc group (RR 1.64).
Management

- patient education
  - symptoms peak at 1-3 d and usually subside within 1 wk
  - cough may persist for days to weeks after other symptoms disappear
  - no antibiotics indicated because of viral etiology
  - secondary bacterial infection can present within 3-10 d after onset of cold symptoms
- prevention
  - frequent hand washing, avoidance of hand to mucus membrane contact, use of surface disinfectant
- symptomatic relief
  - rest, hydration, gargling warm salt water, steam, nasal irrigation (spray/pot)
  - analgesics and antipyretics: acetaminophen, ASA (not in children because risk of Reye's syndrome)
  - cough suppression: dextromethorphan or codeine if necessary (children under 6 yr of age should not use any cough/cold medications)
  - decongestants, antihistamines
  - zinc lozenge use may help to reduced the duration of cold symptoms
- patients with reactive airway disease will require increased use of bronchodilators and inhaled steroids

Contraception

- see Gynecology, GY19

<table>
<thead>
<tr>
<th>Method of Contraception</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Combined OCP</td>
<td>99.9% effective with perfect use, 97-99% with typical use, cycle control, ↓ dysmenorrhea, ↓ menstrual flow, ↓ ovarian cancer, ↓ endometrial cancer, ↓ risk of fibroids, ↓ acne, ↓ hirsutism</td>
<td>Irregular bleeding, systemic hormonal side effects (breast tenderness, nausea, mood changes), no STI protection, slightly increased risk of venous thromboembolism (VTE), MI, stroke, decreased quantity of breast milk postpartum</td>
</tr>
<tr>
<td>Progesterin Only Pill</td>
<td>At least 95% effective with perfect use, no increased risk of VTE, MI or stroke, suitable for postpartum</td>
<td>Hormonal side effects (see Combined OCP)</td>
</tr>
<tr>
<td>Transdermal Patch</td>
<td>Same as OCP, easy to use, changed weekly, 99% effective with correct use</td>
<td>Same as OCP skin irritation</td>
</tr>
<tr>
<td>NuvaRing®</td>
<td>Same as OCP, easy to use (in for 3 wk, out for 1 wk), less systemic hormonal side effects, 99% effective with correct use</td>
<td>Same as OCP vaginitis, some women may be uncomfortable with self-insertion</td>
</tr>
<tr>
<td>IM progesterone injection q12wk</td>
<td>99.7% effective against pregnancy, infrequent dosing, ↓ menstrual flow or amenorrhea, ↓ risk of endometrial cancer</td>
<td>Irregular bleeding, delayed return of fertility, no STI protection, systemic hormonal side effects (most common is headache), weight gain, ↓ bone mineral density (check after 5 yr)</td>
</tr>
<tr>
<td>Male Condom</td>
<td>97% effective against pregnancy and STIs when used properly. When used properly WITH spermicide they are close to 99.9% effective, no Rx required</td>
<td>Latex allergy, irritation, only effective before the expiry date, must be applied properly, can only be used once</td>
</tr>
<tr>
<td>Diaphragm</td>
<td>92-96% effective with perfect use, non-hormonal, female-controlled method of contraception, ↓ risk of cervical cancer</td>
<td>Must be left in for 6 h after intercourse, must be used with spermicide, incomplete STI protection, latex allergy, must be fitted by health care worker, ↑ risk of UTI, risk of toxic shock syndrome</td>
</tr>
<tr>
<td>Sponge</td>
<td>One-size-fits-all barrier method, does not require fitting by MD, available in pharmacies, 90% effective without a condom, 99% effective with a condom</td>
<td>Relatively expensive, only ~60% effective in parous women, incomplete STI protection, risk of toxic shock syndrome</td>
</tr>
<tr>
<td>Intrauterine Device (IUD)</td>
<td>99% effective against pregnancy, effective for 5 yr, no daily regimen required, can be easily removed, ideal in post-partum women</td>
<td>No STI protection, ↑ relative risk of PID in first month, must be inserted by MD, risk of post-insertion vaso-vagal response, risk of uterine rupture is 0.6-1.6 per 1000, 2-10% expulsion rate</td>
</tr>
<tr>
<td>Levonorgestrel (e.g. Mirena®)</td>
<td>Spotting, less systemic hormonal side effects than OCP</td>
<td>Hormonal side effects are possible, but less than OCP (see combined OCP), expensive (~$400)</td>
</tr>
<tr>
<td>Copper IUD (e.g. Nova T®)</td>
<td>↓ risk of endometrial cancer, less expensive than Mirena® (~$170)</td>
<td>Irregular bleeding or ↑ menstrual flow, 6-20% women discontinue use in first 5 yr because of pain or ↑ bleeding</td>
</tr>
<tr>
<td>Fertility Awareness/ Natural Family Planning (e.g. symptothermal method)</td>
<td>Effectiveness: 95-96% with perfect use, 75-98% with typical use, increased awareness of gynecological health, reasonable for couples for whom an unplanned pregnancy would be acceptable</td>
<td>High probability of failure if not used consistently and correctly, no STI protection</td>
</tr>
<tr>
<td>Lactational Amenorrhea</td>
<td>Can be effective in breastfeeding women if menses not returned, fully or nearly fully breastfeeding baby and baby is under 6 mo old</td>
<td>Not effective if infant receives any food supplementary to breastfeeding</td>
</tr>
</tbody>
</table>

Common Presenting Problems

- Management
  - patient education
  - symptomatic relief
  - prophylactic measures

- Contraception
  - see Gynecology, GY19

Echinacea for Preventing and Treating the Common Cold

Cochrane DB Syst Rev 2006;1:CD000530

This systematic review of 16 trials assessed the effect of Echinacea in preventing and treating common colds. Trials compared preparations containing Echinacea with placebo, no treatment, or an alternative common cold treatment. Variations in preparations and quality of Echinacea made meta-analysis difficult, but in general, results suggested some preparations of Echinacea may be better than placebo.

Conclusions: Echinacea preparations vary widely. Some preparations with E. purpurea may be effective but results are inconsistent.
**EMERGENCY CONTRACEPTION (EC)**
- hormonal EC ('Yuzpe' or Plan B®, usually 2 doses taken 12 h apart) or post-coital IUD insertion
- hormonal EC is effective if taken within 72 h of unprotected intercourse (reduces chance of pregnancy by 75-85%), most effective if taken within 24 h, does not affect an established pregnancy
- post-coital IUDs inserted within 5 d of unprotected intercourse are significantly more effective than hormonal EC (reduces chance of pregnancy by ~99%)
- pregnancy test should be performed if no menstrual bleeding within 21 d of either treatment
- advance provision of hormonal EC increases the use of EC without decreasing the use of regular contraception
- pharmacists across Canada can dispense Plan B® OTC

**Cough**

**History and Physical**
- duration (chronic >3 mo), onset, frequency, quality (dry vs. productive), sputum characteristics, provoking/relieving factors, recent changes
- associated symptoms: fever, dyspnea, hemoptyis, wheezing, chest pain, orthopnea, PND, rhinitis
- constitutional symptoms: fever, chills, fatigue, night sweats
- risk factors: smoking, occupation, exposure, family history of lung CA or other CA, TB status, recent travel
- medications (e.g. ACE inhibitors), allergies
- PMH: lung (asthma, COPD, CF), heart (CHF, MI, arrhythmias), chronic illness, GI (reflux)
- vitals including O₂ saturation, respiratory exam, HEENT and precordial exam

**Investigations**
- guided by findings on history and physical
  - consider throat swab, CXR, PFTs, upper GI series, sputum culture test for acid-fast bacilli (if TB is suspected)

**Dementia**

- see Psychiatry, PS20

**Epidemiology**
- 10% in patients over the age of 65, 25% in patients over the age of 85, 50% in patients over the age of 90
- prevalence increases with age. Down syndrome and head trauma
differential diagnosis: Alzheimer’s dementia, vascular dementia, Lewy-Body dementia, frontotemporal dementia

**Investigations**
- history, physical, MMSE, MOCA (best screening test), dementia quick screen (see sidebar)
- investigations are completed to exclude reversible causes of dementia and should be selected based on the clinical circumstances
- CBC, liver enzymes, TSH, renal function tests, serum electrolytes, serum calcium, serum glucose, vitamin B₁₂, folate, VDRL, HIV, single photon emission computed tomography, head CT, EEG

**Management**
- treat and prevent reversible causes
- provide orientation cues (e.g. calendars, clocks) and optimize vision and hearing
- family education, counselling and support (respite programs, group homes)
- pharmacologic therapy: NMDA receptor antagonists and cholinesterase inhibitors slow rate of cognitive decline; low-dose neuroleptics and antidepressants can be used to treat behavioral and emotional symptoms
- 20% of patients develop clinical depression, most commonly seen in vascular dementia

**Depression**

- see Psychiatry, PS9

**Etiology**
- often presents as non-specific complaints (e.g. sleep disturbance, chronic fatigue, pain)
depression is a clinical diagnosis and tests are done in order to rule out other causes of symptoms
- 2/3 of depressed persons may not receive appropriate treatment for their depression
- identification and early treatment improve outcomes

**Absolute Contraindications to Estrogen Containing Contraception (Combined OCP/Transdermal Patch/ Nuvaring)**
- Known/suspected pregnancy
- Undiagnosed abnormal vaginal bleeding
- Thromboembolic disorders (e.g. previous DVT, PE)
- Coronary cardiovascular or coronary artery disease
- Estrogen dependent tumours (breast, uterus)
- Impaired liver function with acute liver disease
- Congenital hyperthriglyceridemia
- Smoker age >35
- Migraines with focal neurological symptoms
- Uncontrolled hypertension

**Differential Diagnosis**

**Common Causes**
- Upper airway cough syndrome (postnasal drip)
- Asthma/COPD
- GERD
- Non-asthmatic eosinophilic bronchitis

**Other Causes**
- ACE inhibitors
- Aspiration
- Bronchectasis
- Cystic fibrosis
- Chronic interstitial lung disease
- CHF
- Lung/laryngeal cancer
- Pertussis
- Psychogenic
- Restrictive lung disease
- TB, atypical mycobacterium, and other chronic lung infections

**Dementia Quick Screen**
- 3 simple tests, takes about 2 min
- Use when suspect mild cognitive impairment or when patient is at high risk
- Screen involves:
  1. 3 word recall (normal = recalls 2-3 words)
  2. Naming animals in 1 min (normal = >12 in one min)
  3. Clock Drawing – including numbers and hands so time shows 10 min past 11 (normal = correct number/hand placing, or only minor spacing problems)

**INTERPRETATION:** If all 3 results within normal range, cognitive impairment unlikely.
If any results abnormal, possible cognitive impairment, further evaluation necessary.

**Must Ask About/Rule Out**
- Bipolar/manic/hypomanic episodes
- Psychosis
- Anxiety
- Bereavement
- Substance use/abuse/withdrawal
- Suicidal/homicidal ideation
- Organic cause
Screening Questions
• Are you depressed? (high specificity and sensitivity)
• Have you lost interest or pleasure in the things you usually like to do? (anhedonia)
• Do you have problems sleeping?
• For geriatric population, use the Geriatric Depression Scale (GDS) short form for screening

Assessment
• risk factors: see Psychiatry, PS11
• personal or family history of depression
• medications and potential substance abuse problems
• high risk suicidality/homicidality
  • fill out Form 1 (in Ontario): application by physician to hospitalize a patient against his/her will for psychiatric assessment (up to 72 h)
  • functional impairment (e.g. work, relationships)
  • at least 5 out of 9 criteria including anhedonia or depressed mood ≥2 wk for actual diagnosis to be met (see sidebar)
• validated depression rating scales: Beck's depression inventory, Zung's self-rating depression scale, Children's depression inventory, Geriatric Depression Scale, Personal Health Questionnaire Depression Scale (PHQ-9)
  • routine medical workup (physical examination, CBC, TSH, electrolytes, urinalysis, glucose, etc.)

Treatment
• goal: full remission of symptoms and return to baseline psychosocial function
• phases of treatment
  • acute phase (8-12 wk): relieve symptoms and improve quality of life
  • maintenance phase (6-12 mo after symptom resolution): prevent relapse/recurrence, must stress importance of continuing medication treatment for full duration to patients
• treatment can consist of pharmacotherapy alone or psychotherapy alone
• combination of antidepressant drug therapy and psychotherapy results in synergistic effects

</tbody>
</table>

Prognosis
• up to 40% resolve spontaneously within 6-12 mo
• risks of recurrence: 50% after 1 episode; 70% after 2 episodes; 90% after 3 episodes

Diabetes Mellitus (DM)

• see Endocrinology, E6

Epidemiology
• major health concern, affecting up to 10% of Canadians
• type 1 diabetes mellitus (DM1): 10-15% of DM, peak incidence age 10-15
• type 2 diabetes mellitus (DM2): 85-90% of DM, peak incidence age 50-55, up to 60,000 new cases in Canada per year
• gestational diabetes mellitus (GDM): 2-4% of all pregnancies
• incidence of type DM2 is rising dramatically as a result of an aging population, rising rates of obesity, and sedentary lifestyles
• leading cause of new-onset blindness and renal dysfunction
• Canadian adults with diabetes are twice as likely to die prematurely, compared to persons without diabetes
Risk Factors
• DM1
  • personal or family history of autoimmune disease
• DM2
  • first degree relative with DM
  • age ≥40 yr
  • obesity (especially abdominal), hypertension, hyperlipidemia, coronary artery disease, vascular disease
  • prior GDM, macrosomic baby (>4 kg)
  • PCOS
  • history of impaired glucose tolerance or impaired fasting glucose
  • presence of complications associated with diabetes
  • presence of associated diseases: PCOS, acanthosis nigricans, psychiatric disorders, HIV
  • medications: glucocorticoids, atypical antipsychotics, HAART
• both
  • member of a high risk population (e.g. Aboriginal, Hispanic, Asian or African descent)

Diagnosis
• persistent hyperglycemia is the hallmark of all forms of diabetes

</tr>
<tr>
<td>Impaired Glucose Tolerance</td>
<td>BG 2 h post 75 g OGTT = 7.8-11.0 mmol/L (141-198 mg/dL)</td>
</tr>
</tbody>
</table>

Screening
• DM2
  • FBG in everyone ≥40 q3yr , or at high risk using the CANRISK calculator
  • more frequent and/or earlier testing if presence of ≥1 risk factor (see above)
• GDM (see Obstetrics, OB14)
  • all pregnant women between 24-28 wk gestation
  • non-fasting 1 h 50 g OGCT ≥10.3 mmol/L (186 mg/dL) is diagnostic
  • if between 7.8-10.2 mmol/L (141-184 mg/dL), do confirmatory fasting 2 h 75 g OGTT
  • if develop GDM, have a 50% chance of developing DM2 over 20 yr

Goals of Therapy

Table 18. Goals of Therapy in DM

| General                           | Avoid complications (e.g. ketoacidosis, hyperglycemia, infection)                     |
|                                  | Prevent long-term complications (microvascular and macrovascular)                   |
|                                  | Minimize negative sequelae associated with therapies (e.g. hypoglycemia, weight gain) |
| Fasting or Preprandial BG        | Ideal: 4-7 mmol/L (72-126 mg/dL); action may be required                              |
|                                  | Suboptimal: 7.1-10 mmol/L (128-180 mg/dL); action required                           |
|                                  | Inadequate: >10.0 mmol/L (180 mg/dL); action required                               |
| HbA1c                             | ≤7% or ≤6.5% in some DM2 patients at risk for nephropathy                             |
|                                  | Suboptimal: 7-8.4%                                                                  |
|                                  | Inadequate: >8.4%                                                                  |
| 2 h Postprandial BG              | 5-10 mmol/L (90-180 mg/dL) if HbA1c target met                                      |
|                                  | 5-8 mmol/L (90-144 mg/dL) if HbA1c target not met                                   |
| Blood Pressure                   | <130/80 in adults (DM and HTN guidelines)                                           |
| Lipids                           | LDL <2.0 mmol/L (38 mg/dL)                                                         |
|                                  | Triglycerides <1.5 mmol/L (27 mg/dL)                                               |
|                                  | Total cholesterol/HDL ratio <4.0 mmol/L (72 mg/dL)                                  |

</table>

### Nonpharmacologic Management

- **diet**
  - all diabetics should see a registered dietitian
  - can reduce HbA1c by 1-2%
  - strive to attain healthy body weight
  - decrease combined saturated fats and trans-fatty acids to <10% of calories
  - avoid simple sugars, encourage complex carbohydrates, choose low glycemic-index foods
- **physical activity and exercise**
  - at least 150 min of aerobic exercise per wk, plus 2 sessions per wk of resistance exercise is recommended
  - encourage 30-45 min of moderate exercise 4-7 d/wk
  - promote cardiovascular fitness: increases insulin sensitivity, lowers BP and improves lipid profile
  - if insulin treated, may require alterations of diet, insulin regimen, injection sites and self-monitoring

### Self-Monitoring of Blood Glucose

- DM1: 3 or more self-tests/d is associated with a 1% reduction in HbA1c
- DM2: at least once per day, if once daily insulin regime
- if FBG >14 mmol/L, perform ketone testing to rule out DKA
- if bedtime level is <7 mmol/L, have bedtime snack to reduce risk of nocturnal hypoglycemia
Calculate Total Insulin Required:

- DM1: 0.5-0.7 units/kg/d
- DM2: 0.3 units/kg/d

Clinical Assessment

- **Lifestyle intervention (initiation of nutrition therapy and physical activity)**

  - **HbA1c < 9.0%**
    - Initiate **metformin**

  - **HbA1c ≥ 9.0%**
    - Initiate **pharmacotherapy** immediately without waiting for effect from lifestyle interventions:
      - Consider initiating **metformin** concurrently with another agent from a different class; or initiate insulin

- **Symptomatic hyperglycemia with metabolic decompensation**

  - Initiate **insulin ± metformin**

  - If not at target
    - Add an agent best suited to the individual based on the advantages/disadvantages listed below

<table>
<thead>
<tr>

*Gaps hypoglycemia in the context of missed meals

**Note:** Physicians should refer to the most recent edition of the Compendium of Pharmaceuticals and Specialties (Canadian Pharmacists Association, Ottawa, Ontario, Canada) for product monographs and for detailed prescribing information

Figure 9. Types of insulin preparation

Figure 10. Management of hyperglycemia in type 2 diabetes

Hypoglycemic Agents (DM2)
- oral
  - biguanide: metformin (Glucophage®)
  - thiazolidinedione: troglitazone (Rezulin®), rosiglitazone (Avandia®)
  - α-glucosidase inhibitor: acarbose (Precose®)
  - nonsulfonylureas: nateglinide (Starlix®), repaglinide (Gluconorm®)
  - sulfonylureas: glyburide (DiaBeta®), gliclazide (Diamicron®)
- injectable
  - GLP-1 analogue: liraglutide (Victoza®)

Other Medications Used in DM
- ACE inhibitors for:
  - all hypertensive diabetics
  - elevated microalbuminuria (30-300 mg albumin in urine in 24 h)
  - overt nephropathy (>300 mg albumin in urine in 24 h)
  - ARBs are second line for these conditions
- ASA 81 mg once a day for:
  - all diabetics, unless contraindicated
- statins
  - as required to attain target lipid profile

Diarrhea
- see Gastroenterology, G15

Definition
- passage of 3 or more loose or liquid stools in a day or more frequently than is normal for the individual (WHO definition)
- can be acute (<14 d duration) or chronic (>14 d duration)

Etiology and Clinical Features
- acute diarrhea:
  - majority of cases are self-limiting
  - most commonly caused by viral infection (e.g. rotavirus, norovirus)
  - fever and bloody stools increase probability of bacterial infection
  - consider C. difficile infection if recent hospitalization, recent antibiotic use (e.g. broad spectrum antibiotics, fluoroquinolones, clindamycin), chronic use of PPIs, age >65, immunosuppression
- chronic diarrhea:
  - most commonly of non-infectious etiology
  - common causes include drugs (e.g. laxatives, antibiotics), infection (e.g. bacteria, parasites), inflammation (e.g. IBD, diverticulitis), neoplasia (e.g. colon cancer), malabsorption (e.g. celiac disease), maldigestion (e.g. lactose intolerance), and idiopathic

Treatment
- acute diarrhea: ensure adequate hydration, treat underlying cause (e.g. antibiotics for bacterial infection)
- chronic diarrhea: nonspecific treatment often required before workup is complete
  - oral rehydration solution (if needed): offset electrolyte imbalances
  - lifestyle modification (dietary changes, exercise)
  - fibre (e.g. psyllium): commonly used as adjunctive treatment
  - antidiarrheal opiates (e.g. loperamide): most effective nonspecific treatment
    - should be used on a scheduled basis before meals rather than prn

Dizziness
- see Otolaryngology, OT5

Epidemiology
- 70% see general practitioners initially; 4% referred to specialists
- frequency proportional to age; commonest complaint of ambulatory patients age >75
Differential Diagnosis

**Dizziness**

- **Vertigo (vestibular)**
  - Objective (external world seems to revolve around individual) or subjective (individual revolves in space)
  - **Central (15%)**
    - Brainstem
    - Cerebellar
  - **Peripheral (85%)**
    - Inner ear (vestibular nerve)
    - Vestibular nerve
    - Idiopathic Meniere’s
    - BPPV
    - Acoustic neuroma
    - Trauma
    - Drugs
    - Labyrinthitis

- **Nonvertiginous (nonvestibular)**
  - Feeling “light-headed,” “giddy,” “dazed,” “mentally confused,” or “disoriented”
  - **Vascular**
    - Basilar migraine
    - TIA
    - Orthostatic hypotension
    - Stokes-Adams syndrome
    - Arhythmia
    - CHF
    - Aortic stenosis
    - Vasovagal episodes
    - Metabolic causes
  - **Ocular**
    - Decreased visual acuity

**Figure 11. Differential diagnosis of dizziness**

**History**
- clarify type of dizziness: vertigo, pre-syncpe, disequilibrium, light-headedness
- onset, precipitating/alleviating factors, preceding infections and activities, associated symptoms, previous experiences of dizziness
- duration (seconds, minutes, hours, days, weeks, or persistent)
- exacerbations
  - worse with head movement or eye closure (vestibular)
  - no change with head movement and eye closure (nonvestibular)
  - worse with exercise (cardiac/pulmonary causes)
- associated symptoms
  - neurologic (central)
    - transient diplopia, dysphagia, dysarthria, ataxia (TIA, VBI, migraine)
    - persistent headache, alterations in level of consciousness, sensory and/or motor deficits (CNS)
  - audiologic (peripheral)
    - hearing loss, tinnitus, otalgia, aural fullness
  - others
    - nausea, vomiting (peripheral vestibular disorders)
    - SOB, palpitations (hyperventilation, cardiac problem)
- general medical history
  - HTN, diabetes, heart disease, fainting spells, seizures, cerebrovascular disease, migraines
  - ototoxic drugs: aminoglycosides (gentamicin, streptomycin, tobramycin), erythromycin, ASA, antimalarials
  - hypotension (secondary to diuresis): furosemide, caffeine, alcohol

**Physical Exam/Investigations**
- syncopal
  - cardiac (orthostatic changes in vitals), peripheral vascular, and neurologic exams
  - bloodwork, ECG, 24-h Holter, treadmill stress test, loop ECG, tilt table testing, carotid and vertebral doppler, EEG
- vertiginous
  - ENT and neurologic exams
  - Dix-Hallpike (see sidebar), consider audiometry and MRI if indicated
- non-syncopal, non-vertiginous
  - cardiac and neurologic exams
  - 3-min hyperventilation trial (patient is coached to hyperventilate until patient becomes dizzy to identify if symptoms are reproducible and confirm that hyperventilation is the etiology of the symptoms), ECG, EEG

**Treatment**
- guided by history, physical and investigations
- include education, lifestyle modification, physical maneuvers (e.g. Epley for BPPV), symptomatic management (e.g. antiemetics), pharmacotherapy and surgery
- refer when significant central disease is suspected, when vertigo of peripheral origin is persistent (lasting >2-4 wk), or atypical presentation
Domestic Violence/Elder Abuse

INTIMATE PARTNER VIOLENCE

Definition
- includes physical, sexual, emotional, psychological and financial abuse
  (see Emergency Medicine, ER29)

Epidemiology
- lifetime prevalence of intimate partner violence against women is between 25-30%
- women who experience abuse have increased rates of injury, death and health consequences
  including 50-70% increase in gynecological, central nervous system, stress-related problems
- occurs in all socioeconomic, educational and cultural groups with increased incidence in
  pregnancy, disabled women, and 18-24 age group
- 25-50% chance of child abuse or neglect in families where partner abuse occurs
- physician recognition rates as low as 5%

Presentation
- multiple visits with vague, ill-defined complaints such as: headaches, gastrointestinal symptoms,
  insomnia, chronic pain, hyperventilation
- may also present with injuries inconsistent with history

Management
- screen ALL patients
  - always have a high index of suspicion
  - physician is often first person to get disclosure
  - health care visits are an important opportunity for physicians to address intimate partner violence
  - asking about abuse is the strongest predictor of disclosure
  - several screening tools (see sidebar) exist to identify victims of partner violence
  - make sure to determine the victim's level of immediate and long term danger and ask if there
    are weapons in the house
  - ensure patient safety
    - victim most at risk for homicide when attempting to leave home or following separation
    - involve social workers or domestic violence advocates
  - provide community resources
    - safety planning includes ensuring that there is access to an exit in the home, establishing a
      safe place to go and having money, clothes, keys, medications, important documents and
      other emergency items prepared should the patient need to leave quickly
    - shelter or helpline number with legal advocacy and counselling services
    - marital counselling inappropriate until safety is established and violence under control
    - appointment for follow-up to assess whether condition is better or worse
    - reassure patient she/he is not to blame and that the assault is a crime
  - goal is to convey the message that “As your doctor, I am concerned for your safety” and
    “Your partner has a problem that he/she needs help with” and “I want to help you”
  - reporting suspected or known child abuse is mandatory (see Emergency Medicine, ER59)
  - spousal abuse is a criminal act, but not reportable without the woman’s/man’s permission
  - DOCUMENT all evidence of abuse-related visits for medico-legal purposes (see sidebar)

ELDER ABUSE

Definition
- mistreatment of elderly by those in a position of trust, power, or responsibility for their care
- types of abuse:
  - psychological (e.g. threatening, intimidating, insulting, demeaning, withholding information
    that may be important to them, ignoring)
  - financial (e.g. stealing, pressuring to sell or share home, misusing power of attorney)
  - physical (e.g. hitting, burning, locking in room, inappropriate use of physical restraints,
    withholding or misusing medication)
  - sexual
  - neglect

Epidemiology
- 7% of adults in Canada age >65 reported experiences of emotional or financial abuse
- older adults who live with someone are more likely to be abused than those who live alone
- 31% of reported violent abuse cases involved family members (Statistics Canada, 2009):
  - most often at the hands of adult children (32%) followed by spouses (28%)
  - older females are more likely to be abused than older males
  - men are more likely than women to be victimized by an adult child (34% vs. 31%)
- women are more likely than men to experience violence at the hands of a spouse (32% vs. 22%)
- reasons for under-reporting: fear, shame, cognitive impairment, language/cultural barriers, and
  social and geographic isolation

How to Document Abuse
- always have a high index of suspicion
- safety planning includes ensuring that there is access to an exit in the home, establishing a
  safe place to go and having money, clothes, keys, medications, important documents and
  other emergency items prepared should the patient need to leave quickly
- shelter or helpline number with legal advocacy and counselling services
- marital counselling inappropriate until safety is established and violence under control
- appointment for follow-up to assess whether condition is better or worse
- reassure patient she/he is not to blame and that the assault is a crime
- goal is to convey the message that “As your doctor, I am concerned for your safety” and
  “Your partner has a problem that he/she needs help with” and “I want to help you”
- reporting suspected or known child abuse is mandatory (see Emergency Medicine, ER59)
- spousal abuse is a criminal act, but not reportable without the woman’s/man’s permission
- DOCUMENT all evidence of abuse-related visits for medico-legal purposes (see sidebar)

Screening Instruments for Domestic Violence
A) Woman Abuse Screening Tool (WAST)-SHORT
1. In general how would you describe your relationship?
   a. A lot of tension
   b. Some tension
   c. No tension
2. Do you and your partner work out arguments with . . .?
   a. Great difficulty
   b. Some difficulty
   c. No difficulty
Endorsing either question 1 ("a lot of tension") or question 2 ("great difficulty") makes intimate partner
violence exposure likely

B) HITS
How often does your partner:
1. Physically hurt you?
2. Insult you?
3. Threaten you with harm?
4. Scream or curse at you?
Each question on HITS to be answered on a 5 point scale ranging from 1
(= never) to 5 (= frequently)
A total score of 10.5 is significant
Screening
- insufficient evidence to include or exclude as part of the periodic health examination, but recommended that physicians be alert for indicators of abuse and institute measures to prevent further abuse
- general questions such as “Do you feel safe at home?” and move into more specific questions about different kinds of abuse

Presentation
- signs that an older adult is being abused may include:
  - depression, fear, anxiety, passivity, unexplained injuries, dehydration, malnutrition, poor hygiene, rashes, pressure sores, and over-sedation/inappropriate medication use

Management
- gather information from all sources (e.g. family members, health care providers, neighbours)
- perform a thorough physical examination
- ensure immediate safety and devise a plan for follow-up
- additional steps depend on whether the patient accepts intervention and whether they are capable of making decisions about their care
- interventions may include use of protective and legal services, senior resource nurses, elder abuse intervention teams and senior support groups

Dyspepsia

Definition and Clinical Features
- defined as epigastric pain or discomfort
- can be associated with fullness, belching, bloating, heartburn, food intolerance, nausea or vomiting

Epidemiology
- annual incidence 1-2%, prevalence 20-40%

Etiology
- common: functional, peptic ulcer disease, gastroesophageal reflux disease (GERD), gastritis
- others: cholelithiasis, irritable bowel syndrome, esophageal or gastric cancer, pancreatitis, pancreatic cancer, Zollinger-Ellison syndrome, and abdominal angina

History
- symptoms may not be useful in finding cause
- association with food, anorexia, nausea, vomiting, NSAID use

Investigations and Management
- lifestyle modifications: dietary changes, decreased EtOH consumption, smoking cessation
- empiric therapy: H₂ receptor blockers, proton pump inhibitors (PPIs) for short periods of time (8 wk with taper)
- testing for H. pylori: serology, urea breath test
- upper endoscopy (preferred), upper GI series

Dyspnea

Definition and Clinical Features
- see Gastroenterology, G10

History and Physical
- history:
  - cough, sputum, hemoptysis, wheezing, chest pain, palpitations, dizziness, edema
  - asthma, allergy, eczema, ASA/NSAID sensitivity, nasal polyps
  - constitutional symptoms
  - smoking, recreational drugs, medications
  - occupational exposure, environmental exposure (e.g. pets, allergens, smoke)
  - travel and birth place
  - FHx of atopy
  - previous CXR or PFTs
- physical exam: vitals, respiratory, precordial, HEENT, signs of anemia/liver failure/heart failure

Investigations
- CXR, ECG
- PFTs, ABG acutely if indicated

Management
- ABCs: send to ER if in severe respiratory distress
- depends on cause

DDx of Dyspepsia
Pulmonary
- COPD
- Asthma
- Restrictive lung disease
- Pneumothorax
- Congenital lung disease

Cardiac
- CHF
- CAD
- MI (recent or past)
- Cardiomyopathy
- Valve dysfunction
- Pericarditis
- Arrhythmia
- Hypertrophy

Mixed/Other
- Deconditioning
- Trauma
- Pain
- Neuromuscular
- Metabolic condition
- Functional: anxiety, panic attack, hyperventilation
Dysuria

- see Urology, U5

Definition

- the sensation of pain, burning or discomfort on urination

Epidemiology

- in adulthood, more common in women than men
- approximately 25% of women report one episode of acute dysuria per year
- most common in women age 25-54 and in those who are sexually active
- in men, dysuria becomes more prevalent with increasing age

Etiology

- infectious
  - most common cause
  - presents as cystitis, urethritis, pyelonephritis, vaginitis or prostatitis
- non-infectious
  - hormonal conditions (hypoestrogenism), obstruction (BPH, urethral strictures), allergic reactions, chemicals, foreign bodies, trauma, neoplasm, kidney stones

Table 20. Etiology, Signs and Symptoms of Dysuria

<table>
<thead>
<tr>
<th>Infection</th>
<th>Etiology</th>
<th>Signs and Symptoms</th>

</tr>
</tbody>
</table>

Investigations

- no investigations necessary when history and physical consistent with uncomplicated UTI – treat empirically (urinalysis can be performed when indicated by dipstick or microscopy)
- urinalysis/dipstick: positive for nitrites and leukocytes
- urine R&M: pyuria, bacteruria, hematuria
- urine C&S
- if vaginal/urethral discharge present: wet mount, Gram stain, KOH test, vaginal pH, culture for yeast and trichomons, endocervical/urethral swab or urine PCR for N. gonorrhoeae and C. trachomatis
- radiologic studies and other diagnostic tests if atypical presentation
- see Pediatrics, P65 for UTI in children

Management

- see Antimicrobial Quick Reference, FM55 for treatment
- UTI/cystitis
  - pregnant women with bacteriuria (2-7%) must be treated even if asymptomatic, due to risk of preterm labour; need to follow with monthly urine cultures and retreat if still infected
  - patients with recurrent UTIs (>3/yr) should be considered for prophylactic antibiotics
  - if complicated UTI, patients require longer courses of broader spectrum antibiotics
  - urethritis
    - when swab or PCR is positive for chlamydia or gonorrhea must report to Public Health
    - all patients should return 4-7 d after completion of therapy for clinical evaluation

UTI Clinical Decision Aid

- Dysuria
  - + Leukocytes
  - + Nitrites

If 2 or more criteria MET, then treat without culture, otherwise culture required prior to treatment.
Arch Intern Med 2007;67:2201-2206

Risk Factors for Complicated UTI

- Male sex
- Pregnancy
- Recent urinary tract instrumentation
- Functional or anatomic abnormality of the urinary tract
- Chronic renal disease
- Diabetes
- Immunosuppression
- Indwelling catheter

Prevention of UTIs

- Maintain good hydration (especially with cranberry juice)
- Wipe urethra from front to back to avoid contamination of the urethra with feces from the rectum
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse

Cranberries for Preventing Urinary Tract Infections

Cochrane DB Syst Rev 2008;1:CD001321
Study: Meta-analysis of 10 RCTs, n = 1049.
Patients: All populations.
Intervention: Cranberry juice vs. placebo, juice or water was evaluated in seven studies, and cranberry tablets vs. placebo in four studies.
Main Outcome: UTIs – symptomatic and asymptomatic.
Results: Cranberry products significantly reduced the incidence of UTIs at 12 mo (RR 0.65, 95% CI 0.46 to 0.90) compared with placebo/control.
Conclusion: There is some evidence that cranberry products may decrease the number of symptomatic UTIs over a 12 mo period, particularly for women with recurrent UTIs.

Investigations

- no investigations necessary when history and physical consistent with uncomplicated UTI – treat empirically (urinalysis can be performed when indicated by dipstick or microscopy)
- urinalysis/dipstick: positive for nitrites and leukocytes
- urine R&M: pyuria, bacteruria, hematuria
- urine C&S
- if vaginal/urethral discharge present: wet mount, Gram stain, KOH test, vaginal pH, culture for yeast and trichomons, endocervical/urethral swab or urine PCR for N. gonorrhoeae and C. trachomatis
- radiologic studies and other diagnostic tests if atypical presentation
- see Pediatrics, P65 for UTI in children

Management

- see Antimicrobial Quick Reference, FM55 for treatment
- UTI/cystitis
  - pregnant women with bacteriuria (2-7%) must be treated even if asymptomatic, due to risk of preterm labour; need to follow with monthly urine cultures and retreat if still infected

### Erectile Dysfunction (ED)

- see Urology, U30

#### Definition
- consistent or recurrent inability to attain and/or maintain penile erection sufficient for sexual performance of ≥3 mo duration

#### Epidemiology
- ~20% of men aged 40; ~50% of men aged 70

#### Etiology
- organic: vascular (90%) (arterial insufficiency, atherosclerosis), endocrine (low testosterone, diabetes), anatomic (structural abnormality, e.g. Peyronie’s), neurologic (post-op, diabetes), medications (clonidine, antihypertensives, psychotropics)
- psychogenic (10%)

#### Table 22. Differentiation Between Organic and Psychogenic ED

*Walsh: Campbell’s Urology, 8th ed. Table 46-4*

#### History
- comprehensive sexual, medical and psychosocial history
- time course
  - last satisfactory erection
  - gradual or sudden onset
  - attempts at sexual activity
quantify (see Table 22, FM31)
- presence of morning or night time erections
- stiffness (scale of 1-10)
- ability to initiate and maintain an erection with sexual stimulation
- erection stiffness during sex (scale of 1-10)

qualify
- partner or situation specific
- loss of erection before penetration or climax
- degree of concentration required to maintain an erection
- percentage of sexual attempts satisfactory to patient and/or his partner
- significant bends in penis or pain with erection
- difficulty with specific positions
- impact on quality of life and relationship

Investigations
- hypothalamic-pituitary-gonadal axis evaluation: testosterone (free + total), prolactin, LH
- risk factor evaluation: fasting glucose, HbA1c, lipid profile
- others: TSH, CBC, urinalysis
- specialized testing
  - psychological and/or psychiatric consultation
  - in-depth psychosexual and relationship evaluation
  - nocturnal penile tumescence and rigidity (NPTR) assessment
  - vascular diagnostics (e.g. doppler studies, angiography)

Management

<table>
<thead>
<tr>
<th>Table 23. Management of Erectile Dysfunction</th>

Eye Complaints
- see Ophthalmology, OP3, for Vision Loss and Red Eye

Falls in the Elderly
- see Geriatric Medicine, GM5

Fatigue

Epidemiology
- 25% of office visits to family physicians
- peaks in ages 20-40
- women 3-4x > men
- 50% have associated psychological complaints/problems, especially if <6 mo duration
Differential Diagnosis

Table 25. Differential Diagnosis of Fatigue: PS VINDICATE

| P | Psychogenic | Depression, sleep disorder, life stresses, anxiety disorder, chronic fatigue syndrome, fibromyalgia |
| S | Sedentary   | Unhealthy/sedentary lifestyle, obstructive sleep apnea |
| V | Vascular    | Stroke |
| I | Infectious  | Any malignancy |
| N | Neoplastic  | Anemia (Fe deficiency, B12 deficiency) |
| D | Drugs       | β-blockers, antihistamines, anticholinergics, benzodiazepines, antiepileptics |
| I | Idiopathic  | Substance abuse (e.g. alcohol), heavy metal |
| C | Chronic Illnesses | CHF, lung diseases (e.g. COPD, sarcoidosis), renal failure, chronic liver disease |
| A | Autoimmune  | SLE, RA, mixed connective tissue disease, polyarthritis rheumatica |
| T | Toxin       | Hypothyroidism, diabetes, Cushing’s syndrome, adrenal insufficiency, pregnancy |
| E | Endocrine   | Any malignancy |

Common causes are in **bold**

Investigations
- Psychosocial causes are common, so usually minimal investigation is warranted
- Physical causes of fatigue usually have associated symptoms/signs that can be elicited from a focused history and physical examination
- Investigations should be guided by history and physical and may include:
  - CBC and differential, electrolytes, BUN, Cr, ESR, glucose, TSH, ferritin, vit B12, serum protein electrophoresis, Bence-Jones, albumin, AST, ALT, ALP, bilirubin, calcium, phosphate, ANA, β-hCG
  - Urinalysis, CXR, ECG
  - Additional tests: serologies (Lyme disease, hepatitis B and C screen, HIV, ANA) and Mantoux skin tests

Treatment
- Treat underlying cause
- If etiology cannot be identified (1/3 of patients)
  - Reassurance and follow-up, especially with fatigue of psychogenic etiology
  - Quick follow-up for reassurance
  - Supportive counselling, behavioural, or group therapy
  - Encourage patient to stay physically active to maximize function
  - Review all medications, OTC, and herbal remedies for drug-drug interactions and side effects
  - Prognosis: after 1 yr, 40% are no longer fatigued

CHRONIC FATIGUE SYNDROME (CFS)

**Definition (CDC 2006)** - must meet both criteria
1. new or definite onset of unexplained, clinically evaluated, persistent or relapsing chronic fatigue, not relieved by rest, which results in occupational, educational, social, or personal dysfunction
2. Concurrent presence of at least 4 of the following symptoms for a minimum of 6 mo:
   - Impairment of short-term memory or concentration, severe enough to cause significant decline in function
   - Sore throat
   - Tender cervical or axillary lymph nodes
   - Muscle pain
   - Multi-joint pain with no swelling or redness
   - New headache
   - Unrefreshing sleep
   - Post-exertion malaise lasting >24 h
- Exclusion criteria: medical conditions that may explain the fatigue, certain psychiatric disorders (depression with psychotic or melancholic features, schizophrenia, eating disorders), substance abuse, severe obesity (BMI >45)

**Epidemiology**
- F>>>M, Caucasians > other groups, majority in their 30s
- Found in <5% of patients presenting with fatigue

**Etiology**
- Unknown, likely multifactorial
- May include infectious agents, immunological factors, neurohormonal factors, and/or nutritional deficiency

**Exercise Therapy for Chronic Fatigue**
Cochrane Depression, Anxiety, and Neurosis Group Cochrane Database of Systematic Reviews 2004, Issue 4

**Purpose:** To determine the effectiveness of exercise therapy for Chronic Fatigue Syndrome (CFS).

**Methods:** Systematic review of 5 RCTs with 336 patients of all ages with a clinical diagnosis of CFS.

**Intervention:** Exercise therapy alone was compared with treatment as usual (or relaxation and flexibility), pharmacotherapy (fluoxetine), or exercise therapy combined with either pharmacotherapy or patient education.

**Results:** At 12 wk, patients undergoing exercise therapy were less fatigued than controls (SMD -0.77; 95% CI, -1.26 to -0.28). Physical functioning was also significantly improved, but there were more dropouts with exercise therapy. Compared with fluoxetine, patients receiving exercise therapy were less fatigued (WMD -1.24; 95% CI, -5.31 to 2.83). Patients receiving combination therapy with exercise therapy and either fluoxetine or patient education, did better than those on monotherapy.

**Conclusions:** Patients may benefit from exercise therapy. Combination therapy with either fluoxetine or education may offer additional benefit. Further high quality trials are needed.
**Investigations**
- no specific diagnostic laboratory tests

**Treatment**
- promote sleep hygiene
- provide support and reassurance that most patients improve over time
- non-pharmacological
  - regular physical activity, optimal diet, psychotherapy (e.g. CBT), family therapy, support groups
- pharmacological
  - to relieve symptoms: e.g. antidepressants, anxiolytics, NSAIDs, antimicrobials, antiallergy therapy, antihypotensive therapy

---

**Fever**

- see *Pediatrics*, P54, for fever in pediatric population

**Definition**
- oral temperature >37.2°C (AM), 37.7°C (PM)
- fever in children under 2 must be a rectal temperature for accuracy
- TM not accurate for measurement until child is over the age of 5

**Table 26. Differential Diagnosis of Fever**

**History**
- fever
  - peak temperature, thermometer, route, duration
  - time of day
  - response to antipyretics
- systemic symptoms
  - weight loss, fatigue, rash, arthralgia, night sweats
- symptoms of possible source
  - UTI/pyelonephritis: dysuria, foul-smelling urine, incontinence, frequency, hematuria, flank pain
  - pneumonia: cough, pleuritic chest pain
  - URTI: cough, coryza, ear pain
  - meningitis: headache, confusion, stiff neck, rash
  - osteomyelitis: bone pain
  - skin: purulent discharge
  - PID: discharge, dyspareunia, lower abdominal pain
  - gastroenteritis: abdominal pain, diarrhea, blood per rectum, vomit
  - medications
  - PE/DVT: swollen legs, pain in calf, shortness of breath, pleuritic chest pain
  - history of cancer/family history of cancer
- infectious contacts
  - travel history, camping, day care, contact with TB, foodborne, animals

**Investigations**
- CBC and differential, blood culture, urine culture, urinalysis
- stool O&P, Gram stain, culture
- CXR, Mantoux skin test, sputum culture
- LP

**Management**
- increase fluid intake
- general: sponge bath, light clothing
- acetaminophen/ibuprofen as needed
- treat underlying cause

---

**Mean Body Temperature**
- Oral = 36.8°C
- Tympanic Membrane = 36.4°C
- Rectal = 37.2°C
- Diurnal Variation = 0.5°C higher at 4 pm vs. 6 am
- See *Pediatrics*, P54 for normal temperature in children

</table>

Secondary Headaches

- caused by underlying organic disease
- account for <10% of all headaches, may be life-threatening
- etiology
  - aneurysm
  - space-occupying lesion
  - systemic infection (meningitis, encephalitis)
  - stroke
  - subarachnoid hemorrhage
  - systemic disorders (thyroid disease, hypertension, pheochromocytoma, etc.)
  - temporal arteritis
  - traumatic head injuries
  - TMJ or C-spine pathology
  - serious ophthalmological and otolaryngological causes of headache
- treatment
  - based on underlying disorder
  - analgesics may provide symptomatic relief

Investigations

- indicated only when red flags are present and may include:
  - CBC for suspected systemic or intracranial infection
  - ESR for suspected temporal arteritis
  - neuroimaging (CT or MRI) to rule out intracranial pathology
  - CSF analysis for suspected intracranial hemorrhage, infection
Hearing Impairment

- see Otolaryngology, OT9

**Definition**
- hearing impairment: a raised hearing threshold measured as decibels of hearing loss relative to the normal population at specific frequencies
- hearing disability: hearing impairment that interferes with performing daily tasks

**Epidemiology**
- 10% of the population is hard of hearing or deaf
- 90% of age-related hearing loss (presbycusis) is sensorineural
- hearing loss detectable by audiology is present in greater than 1/3 of people over 65
- associated with significant physical, functional and mental health consequences

**Classification**
- conductive (sound does not reach cochlea)
- sensorineural (sound is not converted or transmitted via neural signals)
- mixed

**Assessment**
- infants
  - universal newborn hearing screening program
- elderly
  - whispered-voice test
    - whisper six test words 6 inches to 2 feet away from the patient’s ear out of the visual field, ask patient to repeat the words (with non-test ear distraction)
  - tuning fork test
  - Rinne and Weber (not for general screening)
  - audioscope
    - delivers pure tone frequencies to obtain thresholds for frequencies of 250-8000 Hz

**Management**
- counsel about noise control and hearing protection programs (grade A evidence)
- refer patients with hearing loss for a complete audiological examination
- hearing amplification (e.g. hearing aids), assistive listening devices, and cochlear implants can dramatically improve quality of life

Hypertension

**Hypertension Guidelines are reviewed and updated annually.**
*For up to date recommendations, please see www.hypertension.ca/chep*

**Epidemiology**
- 20-25% of Canadian adults have HTN (up to 50% undiagnosed)
- 16% of those diagnosed are well controlled
- approximately 50% of adult Canadians are hypertensive by age 60
- 3rd leading risk factor associated with death

**Definition**
- hypertension
  - BP ≥140/90 mmHg, unless DM (≥130/80 mmHg), or age ≥80 yr (≥150/90 mmHg)
- isolated systolic hypertension
  - sBP ≥140 and dBP <90
  - associated with progressive reduction in vascular compliance
  - usually begins in 5th decade
- accelerated hypertension
  - significant recent increase in BP over previous hypertensive levels associated with evidence of vascular damage on fundoscopy but without papilledema
- malignant hypertension
  - sufficient elevation in BP to cause papilledema and other manifestations of vascular damage (retinal hemorrhages, bulging discs, mental status changes, increasing creatinine)
- not defined by absolute level of BP, but often requires BP of >200/140
- hypertensive urgency
  - sBP >210 or dBP >120 with minimal or no target-organ damage
- hypertensive emergency
  - high BP + acute target-organ damage

Symptoms of hypertension are usually NOT PRESENT (this is why it is called the “silent killer”).
May have occipital headache upon awakening or organ specific complaints if advanced disease.
Etiology
• essential (primary) hypertension (>90%)
  ▪ undetermined cause
• secondary hypertension (10%), see Table 29
• watch for labile, “white coat” hypertension (office-induced elevated BP)

Predisposing Factors
• family history
• obesity (especially abdominal)
• alcohol consumption
• stress
• sedentary lifestyle
• smoking
• male gender
• age >30
• excessive salt intake/fatty diet
• African American ancestry
• dyslipidemia

</table>

Investigations
• for all patients with hypertension
  ▪ CBC, electrolytes, Cr, fasting glucose and lipid profile, 12-lead ECG, urinalysis
• for specific patient subgroups
  ▪ DM OR renal disease: urinary protein excretion
  ▪ increasing Cr OR history of renal disease OR proteinuria OR HTN resistant to 3 meds OR presence of abdominal bruit: renal ultrasound, captopril renal scan, MRA/CTA
  ▪ if suspected endocrine cause: plasma aldosterone, plasma renin
  ▪ if suspected pheochromocytoma: 24 h urine for metanephrines and catecholamines
  ▪ ECG for left ventricular dysfunction assessment if indicated

Hypertensive Emergencies
• Malignant HTN
• Cerebrovascular:
  ▪ Hypertensive encephalopathy
  ▪ CVA with severe hypertension
  ▪ Intracerebral hemorrhage
  ▪ SAH
• Cardiac:
  ▪ Acute aortic dissection
  ▪ Acute refractory LV failure
  ▪ Acute MI with persistent ischemic pain after CABG
• Renal:
  ▪ Acute glomerulonephritis
  ▪ Renal crises from collagen vascular diseases
  ▪ Severe hypertension following renal transplantation
• Excessive circulating catecholamines:
  ▪ Pheochromocytoma
  ▪ Tyramine containing foods or drug interactions with MAOIs
  ▪ Sympathomimetic drug use (e.g. cocaine)
  ▪ Rebound HTN after cessation of anti-hypertensive drugs (e.g. clonidine)
• Eclampsia
• Surgical:
  ▪ Severe HTN prior to emergent surgery
  ▪ Severe post-op HTN
  ▪ Post-op bleeding from vascular suture lines
• HTN following severe burns
• Severe epistaxis

Diagnosis

The Expedited Assessment and Diagnosis of Patients with Hypertension
Focus on Validated Technologies for Blood Pressure Assessment

- Elevated Out-of-the-Office BP Measurement
  - Hypertension Visit 1
    - BP measurement
    - History and physical Examination
    - Diagnostic tests ordering at visit 1 or 2
  - Hypertension Visit 2 within 1 month
    - BP ≥160/110 mmHg
    - OR
    - BP 140-179/90-109 mmHg with target organ damage or diabetes
  - No
  - BP 140-179/90-109 mmHg
  - Elevated Random Office BP Measurement
    - Hypertensive Urgency/Emergency
    - dBP > 120 mmHg or signs of end-organ damage

- Office BPM (OBPM)
  - Hypertension Visit 3
    - ≥160 mmHg sBP or ≥100 mmHg dBP
  - <160 mmHg
    - or
  - <160 mmHg
    - ABPM or HBPM if available
    - Diagnosis of HTN
  - <140 mmHg sBP or ≥90 mmHg dBP
    - Home BPM (HBPM) (if available)
    - Hypertension Visit 4-5
      - ≥140 mmHg sBP or ≥90 mmHg dBP
    - Continue to follow-up
  - <140/90 mmHg
    - Continue to follow-up

- Ambulatory BPM (ABPM) (if available)
  - Awake BP ≥135 mmHg sBP or ≥85 mmHg dBP
    - and
  - ≥24 hour <130/80 mmHg
    - Continue to follow-up
  - <135/85 mmHg
  - Repeat HBPM
  - ≥135 mmHg sBP
  - ≥85 mmHg dBP
    - Diagnosis of HTN

- Diagnosis of HTN

Figure 12. Approach to hypertension
Adapted from: CHEP 2013 Guidelines

Treatment
- target BP is <140/90 mmHg, <130/80 mmHg if DM
- lifestyle modification (in all HTN patients)
  - may be sufficient in patients with stage 1 HTN (140-159/90-99)
  - diet
    - follow Canada’s Guide to Healthy Eating (see Nutrition, FM5) and Dietary Approaches to Stop Hypertension (DASH) (reduced cholesterol and saturated fats)
    - limit daily sodium intake to 65-100 mmol (1.5-2.3 g)
    - potassium/magnesium/calcium supplementations are NOT recommended for HTN
  - moderate intensity dynamic exercise: 30-60 min, 4-7 x/wk; higher intensity exercise is no more effective
  - smoking cessation
  - stress management
  - low-risk alcohol consumption (see Alcohol, FM12)
    - achieve and maintain a healthy BMI and waist circumference; BP will decrease by 4.0/2.8 mmHg for each 4.4 kg of weight loss; use multidisciplinary approach to weight loss
    - individualized cognitive behavioural interventions for stress management
- pharmacological
  - indications regardless of age (caution with elderly patients)
    - dBP ≥90 mmHg with target organ damage or independent cardiovascular risk factors
    - dBP ≥100 mmHg or sBP ≥160 mmHg without target organ damage or cardiovascular risk factors
    - sBP ≥140 with target organ damage

The Effects of Lifestyle Modification on Diet, Weight, Physical Fitness and Blood Pressure Control. 18-month Follow-up Results from the PREMIER Collaborative Research Group
Ann Intern Med 2006;144:485-495

Study: Multicentre, randomized trial.

Patients: 810 adults with prehypertension or stage 1 hypertension (sBP 120-159, dBP 80-95).

Interventions: Multicomponent behavioural intervention using established recommendations (“established”) arm, established recommendations plus the Dietary Approaches to Stop Hypertension (DASH) diet (“established + DASH”) arm, and advice only arm.

Main outcomes: Lifestyle status and blood pressure.

Results: At 18 mo, absolute blood pressures were reduced for both intervention arms compared to advice only but differences were non-significant. The odds for HTN at 18 mo were reduced for both treatment arms compared to advice only. Statistically significant weight loss, fat intake and sodium intake were noted for both treatment arms.

Dieting to Reduce Body Weight for Controlling Hypertension in Adults
Cochrane DB Syst Rev 2008;4:CD000484

A systematic review of 18 trials showed that weight-reducing diets in overweight hypertensive persons can affect modest weight loss in the range of 3-9% of body weight and are probably associated with modest blood pressure decreases of roughly 3 mmHg systolic and diastolic. Weight-reducing diets may decrease dosage requirements of persons taking antihypertensive medications.
• first line antihypertensives: thiazide, ACEI, ARB, CCB, β-blocker (if age <60)
• if partial response to standard dose monotherapy, add another first-line drug
• caution with combination of non-DHP CCB and β-blocker
• combination of ACEI and ARB is not recommended
• if still not controlled or adverse effects, can add other classes of anti-hypertensives

Table 30. Pharmacologic Treatment of Hypertension in Patients with Unique Conditions

<table>
<thead>
<tr>
<th>Condition or Risk Factor</th>
<th>Recommended Drugs</th>
<th>Alternative Drugs</th>
<th>Not Recommended/Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Isolated Diastolic HTN</td>
<td>Thiazide diuretic, β-blocker, ACEI, ARB, or long-acting CCB (consider ASA and statin in select patients)</td>
<td>Combinations of first-line drugs</td>
<td>β-blocker monotherapy (age &gt;60) or combination of ACEI with an ARB</td>
</tr>
<tr>
<td>Isolated Systolic HTN</td>
<td>Thiazide diuretic, ARB or long acting dihydropyridine CCB</td>
<td>Combinations of first-line drugs</td>
<td>Same as above</td>
</tr>
<tr>
<td>Coronary Artery Disease</td>
<td>ACEI or ARB; β-blocker for patients with stable angina</td>
<td>Long acting CCB, when combination therapy for high risk patients, ACEI/DHP CCB is preferred</td>
<td>Short-acting CCB (nifedipine) or ACEI + ARB is not recommended</td>
</tr>
<tr>
<td>Prior MI</td>
<td>β-blocker + ACEI (ARB if can’t tolerate ACEI)</td>
<td>Long-acting CCB</td>
<td>ACEI + ARB combination is not recommended</td>
</tr>
<tr>
<td>Left Ventricular Hypertrophy</td>
<td>ACEI, ARB, thiazide, or long-acting CCB</td>
<td>Combination of additional agents</td>
<td>Hydralazine and minoxidil can increase LVH, thus not recommended</td>
</tr>
<tr>
<td>Cerebrovascular Disease (stroke/TIA)</td>
<td>ACEI + diuretic</td>
<td>Combination of additional agents</td>
<td>ACEI + ARB combination after a stroke is not recommended</td>
</tr>
<tr>
<td>Heart Failure</td>
<td>ACEI (ARB if ACEI intolerant) and β-blocker</td>
<td>ARB in addition to ACEI. Hydralazine/orosorbide dinitrate combination if ARB or ACEI not tolerated/contraindicated</td>
<td>Non-DHP CCB not recommended. Carefully monitor for side effects if using ACEI + ARB</td>
</tr>
<tr>
<td>Dyslipidemias</td>
<td>Does not affect initial treatment recommendations</td>
<td>Combination of additional agents</td>
<td>ACEI + ARB combination after a stroke is not recommended</td>
</tr>
<tr>
<td>Diabetes Mellitus with Albuminuria (ACR &gt;2.0 mg/mmol in men and &gt;2.8 mg/mmol in women)</td>
<td>ACEI or ARB</td>
<td>Add thiazide diuretic, cardioselective β-blocker, long acting CCB</td>
<td>If serum Cr &gt;150 μmol/L, a loop diuretic should be considered instead of low-dose thiazide diuretic</td>
</tr>
<tr>
<td>Diabetes Mellitus without Albuminuria (criteria listed above)</td>
<td>ACEI, ARB, DHP CCB, or thiazide diuretic</td>
<td>Combination of first-line drugs or, first-line agents not tolerated, cardioselective β-blocker or non-DHP CCB</td>
<td>ACEI + ARB combination not recommended</td>
</tr>
<tr>
<td>Non-diabetic Chronic Kidney Disease with Proteinuria (urinary protein &gt;500 mg/24 h or ACR &gt;30 mg/mmol)</td>
<td>ACEI (ARB if ACEI intolerant), diuretic as additive therapy</td>
<td>Thiazide for additive antihypertensive therapy, loop diuretic for volume overload</td>
<td>ACEI + ARB combination is not recommended</td>
</tr>
<tr>
<td>Renovascular Disease</td>
<td>Same as HTN without other indications</td>
<td></td>
<td>Caution in using ACEI or ARB – monitor for AKI</td>
</tr>
<tr>
<td>Asthma</td>
<td>K+- sparing + thiazide diuretic for patients on salbutamol</td>
<td></td>
<td>β-blocker, unless specific indications like angina or post-MI</td>
</tr>
<tr>
<td>Gout</td>
<td>Thiazide, but asymptomatic hyperuricemia is not a contraindication</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Smoking</td>
<td>Low dose thiazide</td>
<td></td>
<td>β-blocker</td>
</tr>
<tr>
<td>Pregnancy</td>
<td>Methyldopa</td>
<td>Hydralazine</td>
<td>Labetolol, nifedipine</td>
</tr>
<tr>
<td>Elderly (≥60)</td>
<td>As for uncomplicated diastolic HTN, except for use of β-blocker</td>
<td></td>
<td>β-blocker not recommended as first line treatment</td>
</tr>
<tr>
<td>Emergency</td>
<td>BP &gt;169/90 = labetolol, nifedipine</td>
<td></td>
<td></td>
</tr>
<tr>
<td>If ≥3 cardiovascular risk factors or established atherosclerotic disease</td>
<td>Statin, ASA</td>
<td></td>
<td>Caution with use of ASA in patients with uncontrolled BP</td>
</tr>
</tbody>
</table>

Follow-Up
- assess and encourage adherence to pharmacological and non-pharmacological therapy at every visit
- lifestyle modification → q3-6mo
- pharmacological
  - q1-2mo until BP under target for 2 consecutive visits
  - more often for symptomatic HTN, severe HTN, antihypertensive drug intolerance, target
    organ damage
  - q3-6mo once at target BP
- referral is indicated for cases of refractory hypertension, suspected secondary cause or
  worsening renal failure
- hospitalization is indicated for malignant hypertension

Low Back Pain
- see Orthopedics, OR22
- see www.bigbackpain.com for more information

Definition
- acute: <6 wk
- subacute: 6-12 wk
- chronic: >12 wk

Epidemiology
- 5th most common reason for visiting a physician
- lifetime prevalence: 90%
- peak prevalence: age 45-60
- largest WSIB category
- most common cause of chronic disability for individuals <45 yr old
- 90% resolve in 6 wk, <5% become chronic

Etiology
- source of pain can be local, radicular, referred, or related to a psychiatric illness
- 98% are mechanical causes
  - pain is worse with movement, better with rest
  - sprain (ligament), strain (muscle), facet joint degeneration, disc degeneration/herniation,
    spinal stenosis (e.g. spondylolisthesis), compression fracture, pregnancy
- 2% are non-mechanical causes
  - most concerning when pain is worse at rest and does not change with position
  - surgical emergencies:
    - cauda equina syndrome (areflexia, lower extremity weakness, decreased anal tone, saddle
      anesthesia, fecal incontinence, urinary retention), AAA (pulsatile abdominal mass)
  - medical conditions:
    - neoplastic (primary, metastatic, multiple myeloma)
    - infectious (osteomyelitis, TB)
    - metabolic (osteoporosis, osteomalacia, Paget's disease)
    - rheumatologic (ankylosing spondylitis, polymyalgia rheumatica)
    - referred pain (perforated ulcer, pancreatitis, pyelonephritis, ectopic pregnancy, herpes
      zoster)

Physical Exam
- neurologic exam for L4/L5/S1 helps determine level of spinal involvement (power, reflexes,
  sensation)
- posture, gait, ROM and peripheral pulses
- percussion of spine to illicit fracture or infection
- special tests
  - straight leg raise (positive if pain at <70 degrees and aggravated by ankle dorsiflexion),
    positive test is indicative of sciatica
  - crossed straight leg raise (raising of uninvolved leg elicits pain in leg with sciatica), more
    specific than straight leg raise
  - femoral stretch test (patient prone, knee flexed, examiner extends hip) to diagnose L4
    radiculopathy

Investigations
- plain films not recommended in initial evaluation
- if infection/cancer suspected: CBC, ESR
- if neurologic deficits worsening or infection/cancer suspected: consider CT or MRI

Red Flags for Back Pain
- Bowel or bladder dysfunction
- Anesthesia (saddle)
- Constitutional symptoms/malignancy
- Paresthesias
- Age >50 and mild trauma
- IV drug use/infection
- Neurologic deficits

Yellow Flags for Back Pain
- Psychosocial barriers to recovery that may indicate the risk of long-term disability and work loss
  - Belief that pain and activity are harmful
  - Negative or low mood, social withdrawal
  - Problems with claim and compensation
  - History of back pain, time off, and/or other claims
  - Poor job satisfaction
  - Overprotective family or lack of support
  - Persistent pain for 4-6 wk with little to no improvement in symptoms

Indications for Lumbar Spine X-ray
- No improvement after 6 wk
- Fever >38°C
- Unexplained weight loss
- Prolonged corticosteroid use
- Significant trauma
- Progressive neurological deficit
- Suspicion of ankylosing spondylitis
- History of cancer (rule out metastases)
- Alcohol/drug abuse (increased risk of osteomyelitis, trauma, fracture)
Menopause/Hormone Replacement Therapy (HRT)

- see Gynecology, GY32

Epidemiology

- mean age of menopause = 51.4 yr
- a woman will spend over 1/3 of her life in menopause

Clinical Features

- associated with estrogen deprivation
- urogenital tract: atrophy, vaginal dryness/itching, urinary frequency/urgency/incontinence, bleeding
- blood vessels and heart: vasomotor instability (e.g., hot flashes), increased risk of heart disease
- bones: bone loss, joint/muscle/back pain, fractures, loss of height
- brain: depression, irritability, mood swings, memory loss
Management
- encourage physical exercise, smoking cessation, and a balanced diet with adequate intake/supplementation of calcium (1200-1500 mg/d) and vitamin D (800-2000 IU/d)
- hormone replacement therapy (HRT)
  - prescribe for moderate to severe symptoms for no longer than 5 yr; routine use is not recommended
  - regimens: cyclic estrogen-progestin, continuous estrogen-progestin, estrogen only (if no uterus), estrogen patch/gel/cream/ring/vaginal tablet
- decreases risk of osteoporotic fractures, colorectal cancer
- increases risk of breast cancer, coronary heart disease, stroke, DVT, and PE
- initiation of HRT requires a thorough discussion of short- and long-term benefits and risks
- consider venlafaxine, SSRIs, or gabapentin to ease vasomotor instability

Osteoarthritis

- see Rheumatology, RH5

Epidemiology
- most common form of arthritis seen in primary care
- prevalence is 10-12% and increases with age
- results in long-term disability in 2-3% of patients with OA
- almost everyone over the age of 65 shows signs of OA on x-ray, but only 33% of these individuals will be symptomatic

Clinical Features
- joint pain with activity, improved with rest, morning stiffness or gelling <30 min
- deformity, bony enlargement, crepitus, limitation of movement, peri-articular muscle atrophy
- usually affects distal joints of hands, spine, hips, and knees

Investigations
- no laboratory tests for the diagnosis of OA
- hallmark radiographic features: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes

Management
- goals: relieve pain, preserve joint motion and function, prevent further injury
  - conservative
    - patient education, weight loss, low-impact exercise (OT/PT), assistive devices (e.g. canes, orthotics, raised toilet seats)
  - pharmacological
    - consider comorbidities such as PUD, HTN, IHD, hepatic disease, and renal disease
    - medications do not alter natural course of OA
    - 1st line: acetaminophen up to 4 g/d (OA is not an inflammatory disorder)
    - 2nd line: NSAIDs in the lowest effective dose for the shortest duration of time, along with gastroprotection; COX-2 selective inhibitors (celecoxib/Celebrex®, Meloxicam/Mobicox®) are recommended if long-term treatment or if high risk for serious GI problems
    - combination analgesics (e.g. acetaminophen and codeine)
    - intra-articular corticosteroid injections (no more than 3-4x/yr) may be helpful in acute flares (benefits last 4-6 wk, can be up to 6 mo)
    - topical NSAID (diclofenac/Pennsaid®)
    - capsaicin cream (Zostrix®)
    - oral glucosamine
  - surgery
    - consider if persistent significant pain and functional impairment despite optimal pharmacotherapy (e.g. debridement, osteotomy, total joint arthroplasty)

Osteoporosis

- see Endocrinology, E42

for current guidelines see www.osteoporosis.ca
- age-related disease characterized by decreased bone mass and increased susceptibility to fractures
- affects 1 in 4 Canadian women and 1 in 8 Canadian men
Encourage basic bone health for all individuals over age 50, including regular active weight-bearing exercise, calcium (diet and supplements) 1200 mg daily, vitamin D 800-2000 IU (20-50 µg) daily and fall-prevention strategies

Adapted from CMAJ 2010;182:1864-1873

Disorders Strongly Associated with Osteoporosis include:
- Primary hyperparathyroidism, DM1, osteogenesis imperfecta, uncontrolled hyperthyroidism, hypogonadism or premature menopause (≤45 yr).
- Cushing’s disease, chronic malnutrition or malabsorption, chronic liver disease, COPD and chronic inflammatory conditions (e.g. IBD)

10-yr Fracture Risk Assessment
FRAX (WHO Fracture Risk Assessment Tool) and CAROC (Canadian Association of Radiologists and Osteoporosis Canada) have been validated in the Canadian Population

How much Calcium do we Need?
- 4-8 1000 mg
- 9-18 1300 mg
- 19-50 1200 mg
- >50 1200 mg
- Pregnant and lactating women 1000 mg

Calcium Content of Common Foods
- 1 cup milk = 300 mg
- ¼ cup yogurt = 332 mg
- ⅓ can salmon with bones = 240 mg
- ½ cup cooked broccoli = 33 mg
- 1 medium orange = 50 mg

Vitamin D Content of Common Foods
- Milk fortified with vitamin D3 contains 100 IU/s per 250 mL glass.
- Foods such as margarine, eggs, chicken livers, salmon, sardines, herring, mackerel, swordfish and fish oils (halibut and cod liver oils) all contain small amounts.
- Supplementation is necessary to obtain adequate levels as dietary intake has minimal impact.
- Most multivitamins provide 400 IU of vitamin D3

Figure 14. 2010 Clinical practice guidelines for the diagnosis and management of osteoporosis in Canada (integrated management model). Adapted from CMAJ 2010;182:1864-1873

Management
- Falls prevention: home safety assessment, optimize vision (e.g. cataract removal), consider hip protectors in older adults living in long-term care facilities
- Exercise: weight-bearing, balance, and strengthening exercises as appropriate for the patient’s age and functional capacity
- Habits: smoking cessation, decrease alcohol intake
- Diet: calcium 1200 mg/d through diet and supplements; vitamin D 400-1000 IU/d if healthy and at low risk of deficiency, 800-2000 IU/d if >50 yr and moderate risk of deficiency
- Pharmacological
  - Vertebral, hip, and non-vertebral fractures: bisphosphonates (alendronate, risedronate, zoledronate), monoclonal Ab (denosumab), estrogen (first line in women with menopausal symptoms)
  - Vertebral fractures only: SERM (raloxifene)
• for postmenopausal women, ✓ indicates first-line therapies (grade A)
• for men, alendronate, risedronate, and zoledronate can be used as first-line therapies for prevention of fractures (grade D)
• non-vertebral fractures: hip, femur, pelvis, tibia, humerus, radius, clavicle
• estrogen can be used as first-line therapy in women with menopausal symptoms but the risks may outweigh the benefits (see Gynecology, GY33)
• reflux, esophagitis, and esophageal ulcers are the major side effects of oral bisphosphonates

Rash
• see Dermatology, D5

**ATOPIC DERMATITIS**
• clinical features
  - affects all ages but is more common in children
  - pruritus is the most common symptom; scratching worsens the rash, creating a vicious cycle
• treatment
  - goals: limit itching, repair skin
  - moisturizers, emollients, topical corticosteroids; oral corticosteroids and topical calcineurin inhibitors may be used

**SEBORRHEIC DERMATITIS**
• clinical features
  - affects all ages but is most common in infants within the first 3 months of life (e.g. pityriasis capitis or "cradle cap") and adults age 30-60 yr
  - affects the scalp, central face, and anterior chest; often presents as scalp scaling (dandruff) in adolescents and adults
  - may cause mild to marked erythema of the nasolabial fold, often with greasy scaling
• treatment
  - topical antifungals, topical low-potency steroids; topical calcineurin inhibitors may be used

**ROSACEA**
• clinical features
  - stages: (1) facial flushing, (2) erythema and/or edema and ocular symptoms, (3) papules and pustules, (4) rhinophyma
• treatment
  - topical or oral antibiotics, oral retinoids
  - laser treatment may be an option for progressive telangiectasis or rhinophyma
  - referral may be required to manage rhinophyma, ocular complications, or severe disease

**ACNE VULGARIS**
• clinical features
  - types: (I) comedonal, (II) papular, (III) pustular, (IV) nodulocystic
  - predilection for the face, neck, upper chest, and back
• treatment
  - mild acne: topical treatments (antibiotics, benzoyl peroxide, retinoids)
  - moderate acne: after topical treatments have failed, add oral antibiotics and consider hormonal therapy
  - severe acne: consider systemic retinoids

**ONYCHOMYCOSIS (TINEA UNGUIUM)**
• definition: fungal infection of the nail bed, matrix, or plate
• clinical features
  - occurs primarily in adults, most commonly after age 60 yr
  - crumbling, distally dystrophic nails; yellowish, opaque with subungual hyperkeratotic debris; toenails are affected more often than fingernails
• investigations
  - microscopy of subungual scrapings under KOH preparation, culture
• treatment
  - oral antifungals (terbinafine/Lamisil®, itraconazole/Sporanox®), topical antifungals (ciclopirox/Loprox®)
## Rhinorrhea

- see [Otolaryngology, OT22](#)

### Differential Diagnosis
- common cold, sinusitis, influenza, strep pharyngitis, ear infection, vasomotor rhinitis
- allergies, contact with substances, tearing
- foreign body
- opioid withdrawal
- basilar skull fracture

### Investigations
- CBC, throat swab, nasopharyngeal swab, x-ray if injury, allergy testing

### Management
- nasal saline rinse
- consider medications: antihistamines, decongestants, corticosteroid nasal spray

---

## Sexually Transmitted Infections (STIs)

- see [Gynecology, GY26](#)

### Definition
- diverse group of infections caused by multiple microbial pathogens
- transmitted by either secretions or fluids from mucosal surfaces

### Epidemiology
- high incidence rates worldwide
- Canadian prevalence in clinical practice
  - common: chlamydia (most common), gonorrhea (2nd most common), HPV, genital herpes (increasing incidence of chlamydia and gonorrhea)
  - less common: hepatitis B, HIV and syphilis (both increasing in incidence), trichomoniasis
  - rare: chancroid, granuloma inguinale, lymphogranuloma venereum
- non-sexually transmitted genital tract infections: vulvovaginal candidiasis (VVC), bacterial vaginosis (BV)
- three most common infections associated with vaginal discharge in adult women are BV, VVC, and trichomoniasis

### History
- sexual history
  - age of first intercourse, sexual orientation, sexual activity (oral, anal, and/or vaginal intercourse), sexual activity during travel
  - total number of partners in the past year/month/week and duration of involvement with each
- STI history
  - STI awareness, contraception, previous STIs and testing (including pap tests), partner communication regarding STIs
  - local symptoms such as burning, itching, discharge, sores, vesicles, testicular pain, dysuria, abdominal pain
  - systemic symptoms such as fever, lymphadenopathy, arthralgia

### Investigations/Screening
- individuals at increased risk, even those who are asymptomatic, should be screened for chlamydia, gonorrhea, hepatitis B, HIV, and syphilis
- Pap test if none performed in the preceding 12 mo

### Management
- primary prevention is vastly more effective than treating STIs and their sequelae
- offer hepatitis B vaccine if not immune, offer Gardasil® to women under age 26
- discuss STI risk factors (e.g. decreasing the number of sexual partners)
- direct advice to ALWAYS use condoms or to abstain from intercourse
- condoms are not 100% effective against HPV or HSV
- an STI patient is not considered treated until the management of his/her partner(s) is ensured
- patients should abstain from sexual activity until treatment completion and for 1 mo afterwards or until test of cure completed
- mandatory reporting: chlamydia, gonorrhea, hepatitis B, HIV, syphilis

---

**Prophylactic Vaccination Against Human Papillomavirus Infection and Disease in Women: A Systematic Review of Randomized Controlled Trials**

*CMAJ 2007;177:469-479*

**Purpose:** To evaluate prophylactic HPV vaccination in preventing high- and low-grade cervical lesions, persistent HPV infection, external genital lesions, adverse events, and death using meta-analysis.

**Studies:** 9 reports from 6 different trials with 40,323 patients were included and all studies were of high methodologic quality. Three studies used the quadrivalent vaccine, two used the bivalent, and one used a monovalent. The longest mean duration of follow-up was 48 mo.

**Results:** Prophylactic HPV vaccination decreased the frequency of high-grade cervical lesions caused by vaccine-type HPV strains compared to the control group (OR 0.14 (95% CI 0.09-0.21)). Vaccinations also prevented persistent HPV infection, low-grade lesions and genital warts and the reported adverse events were mostly minor. Compared to placebo, there was no difference in serious adverse events or death.

**Conclusion:** Prophylactic HPV vaccination is highly efficacious in preventing infection and precancerous cervical disease in women aged 15-25 who have not previously been infected with vaccine-type HPV strains.
Management of Acute Sinusitis

- may provide symptom relief: oral analgesics (acetaminophen, NSAIDs), nasal saline rinse, short-term use of topical or oral decongestants
- do not prescribe antihistamines
- intra-nasal corticosteroids if diagnosed with mild to moderate acute bacterial sinusitis
- antibiotics and intra-nasal corticosteroids if diagnosed with severe acute bacterial sinusitis
- ENT referral if: anatomic defect (e.g. deviated septum, polyp, adenoid hypertrophy), failure of second-line therapy, ≥4 episodes/yr, development of complications (e.g. mucocele, orbital extension, meningitis, intra-cranial abscess, venous sinus thrombosis)

don't prescribe antihistamines
intra-nasal corticosteroids if diagnosed with mild to moderate acute bacterial sinusitis
antibiotics and intra-nasal corticosteroids if diagnosed with severe acute bacterial sinusitis
ENT referral if: anatomic defect (e.g. deviated septum, polyp, adenoid hypertrophy), failure of second-line therapy, ≥4 episodes/yr, development of complications (e.g. mucocele, orbital extension, meningitis, intra-cranial abscess, venous sinus thrombosis)
Figure 15. Diagnosis and management of sinusitis
ABRS = acute bacterial rhinosinusitis

Sleep Disorders

- see Respirology, R31 and Neurology, N41

Definition
- most often characterized by one of three complaints:
  - insomnia
    - difficulty falling asleep, difficulty maintaining sleep, early-morning wakening, non-refreshing sleep
  - parasomnias
    - night terrors, nightmares, restless leg syndrome, somnambulism (performing complex behaviour during sleep with eyes open but without memory of event)
  - excessive daytime sleepiness

Epidemiology
- 1/3 of patients in primary care setting have occasional sleep problems, 10% have chronic sleep problems
Etiology
- primary sleep disorders
  - primary insomnia, narcolepsy, obstructive sleep apnea, restless leg syndrome, periodic limb movements of sleep
- secondary causes
  - medical: COPD, asthma, CHF, hyperthyroidism, chronic pain, BPH, menopause, GERD, PUD
  - drugs: alcohol, caffeine, nicotine, nicotine replacement therapy, β-agonists, antidepressants, steroids
  - psychiatric: especially mood and anxiety disorders
  - lifestyle factors: shift work

Investigations
- complete sleep diary every morning for 1-2 wk
  - record bedtime, sleep latency, total sleep time, awakenings, quality of sleep
- rule out specific medical problems (e.g. CBC and differential, TSH)
- refer for sleep study, nocturnal polysomnogram, or daytime multiple sleep latency test if suspicion of sleep apnea or periodic leg movements of sleep

Treatment
- treat any suspected medical or psychiatric cause
- psychologic treatment
  - sleep hygiene: avoid alcohol, caffeine, nicotine; comfortable sleep environment; regular sleep schedule; no napping
  - exercise regularly, avoid heavy exercise within 3 h of bedtime
  - relaxation therapy: deep breathing, meditation, biofeedback
  - stimulus control therapy: re-association of bed/bedroom with sleep, re-establishment of a consistent sleep-wake schedule, reduce activities that cue staying awake
  - sleep restriction therapy: total time in bed should closely match the total sleep time of the patient (improves sleep efficacy)
  - CBT: address inappropriate beliefs and attitudes that perpetuate dysfunctional sleep
- pharmacologic treatment
  - short-acting benzodiazepines (e.g. lorazepam, oxazepam, temazepam) at the lowest effective dose should be used <7 consecutive nights to break cycle of chronic insomnia or to manage an exacerbation of previously controlled primary insomnia
  - non-benzodiazepines: zopiczone (Imovane®)
  - F/U every 2-4 wk initially (to reinforce behavioural interventions and renew/consider pharmacotherapy) then every 3 mo; if no progress or limited improvement, consider referral to sleep medicine program

Specific Problems
- primary insomnia
  - majority of cases
  - person reacts to insomnia with fear or anxiety around bedtime or with a change in sleep hygiene, which can progress to a chronic disorder (psychophysiological insomnia)
- snoring
  - results from soft tissue vibration at the back of the nose and throat due to turbulent airflow through narrowed air passages
  - physical exam: obesity, nasal polyps, septal deviation, hypertrophy of the nasal turbinates, enlarged uvula and tonsils
  - investigations (only if severely symptomatic): nocturnal polysomnography and airway assessment (CT/MRI)
  - treatment
    - sleep on side (position therapy), weight loss
    - nasal dilators (noninvasive external dilator made with elastic adhesive backing applied over nasal bridge), tongue-retaining devices, mandibular advancement devices
    - at risk of developing obstructive sleep apnea
- obstructive sleep apnea (OSA)
  - apnea (no breathing for ≥10 s) resulting from upper airway obstruction due to collapse of the base of the tongue, soft palate with uvula, and epiglottis; respiratory effort is present; leads to a distinctive snorting, choking, awakening type pattern as the body rouses itself to open the airway (resuscitative breath)
  - apneic episodes can last from 20 s to 3 min and occur 100-600 episodes/night
  - diagnosis is based on nocturnal polysomnography: >15 apneic/hypopneic episodes per hour of sleep with arousal recorded
  - consequences
    - daytime somnolence, non-restorative sleep
    - poor social and work performance

Risk Factors for Insomnia
- Older age
- Female
- Unemployed or less educated
- Separated or divorced
- Medical comorbidities
- Depression
- Anxiety
- Substance abuse

Risk Factors for Snoring
- Male
- Obesity
- Alcohol consumption
- Smoking
- Use of tranquilizers or muscle relaxants

Risk Factors for Obstructive Sleep Apnea
- 2% of women, 4% of men between ages 30-60
- Obesity (due to upper airway narrowing), BMI ≥28 kg/m² present in 60-90% of cases
- Children (commonly due to large tonsils and adenoids)
- Aging (due to decreased muscle tone)
- Persistent URI's, allergies, nasal tumours, hypothryoidism (due to macroglottis), neuromuscular disease
- Family history
• mood changes: anxiety, irritability, depression
• sexual dysfunction: poor libido, impotence
• morning headache (due to hypercapnia)
• HTN (2x increased risk), CAD (3x increased risk), stroke (4x increased risk), arrhythmias
• pulmonary HTN, right ventricular dysfunction, cor pulmonale (due to chronic hypoxemia)
• memory loss, decreased concentration, confusion

• investigations
  • evaluate BP, inspect nose and oropharynx (enlarged adenoids or tonsils)
  • blood gas not helpful, TSH if clinically indicated
  • nocturnal polysomnography

• treatment
  • modifiable factors: avoid sleeping supine; weight loss; avoid alcohol, sedatives, opioids; inhaled steroids if nasal swelling present; dental appliances to modify mandibular position
  • primary treatment of OSA is CPAP: maintains patent airway in 95% of OSA cases
  • surgery: somnoplasty, uvulopalatopharyngoplasty (UPPP), tonsillectomy and adenoidectomy (in children)
  • report patient to Ministry of Transportation if OSA is not controlled by CPAP

• central sleep apnea
  • definition
    • brain fails to send appropriate signals to the breathing muscles to initiate respirations
    • defining feature is absent respiratory effort
  • often secondary to CNS diseases: brainstem infarction, infection, neuromuscular disease
  • investigations: PFTs, nocturnal polysomnography, MRI
  • treatment: CPAP or mechanical ventilation (if brainstem origin)
  • prognosis: poor

---

Sore Throat (Pharyngitis)

**Definition**
- inflammation of the oropharynx
- may be caused by a wide range of infectious organisms, most of which produce a self-limited infection with no significant sequelae

**Etiology**
- viral: adenovirus, rhinovirus, influenza virus, RSV, EBV, coxsackie virus, herpes simplex virus, CMV, HIV
- bacterial: group A β-hemolytic Streptococcus (GABHS), group C and G β-hemolytic Streptococcus, Neisseria gonorrhoeae, Chlamydia pneumoniae, Mycoplasma pneumoniae, Corynebacterium diphtheriae

**Epidemiology**
- viral
  - most common cause, occurs year round
- bacterial
  - GABHS
    - most common bacterial cause
    - occurs most often in winter months
    - 5-15% of adult cases and up to 50% of all pediatric cases of acute pharyngitis
    - most prevalent between 5-17 yr old

**Clinical Features**
- viral
  - pharyngitis, conjunctivitis, rhinorrhea, hoarseness, cough
  - nonspecific flu-like symptoms such as fever, malaise, and myalgia
  - often mimics bacterial infection
  - EBV (infectious mononucleosis)
    - pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash
  - coxsackie virus (hand, foot and mouth disease)
    - primarily late summer, early fall
    - sudden onset of fever, pharyngitis, headache, abdominal pain and vomiting
    - appearance of small vesicles that rupture and ulcerate on soft palate, tonsils, pharynx
    - ulcers are pale grey and several mm in diameter, have surrounding erythema, and may appear on hands and feet
  - herpes simplex virus
    - like coxsackie virus but ulcers are fewer and larger
    - pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash

---

Red Flags in Patients with “Sore Throat”
- Persistence of symptoms longer than 1 wk without improvement
- Respiratory difficulty (particularly stridor, croup, etc.)
- Difficulty in handling secretions (peritonsillar abscess)
- Difficulty in swallowing (Ludwig’s angina)
- Severe pain in the absence of erythema (supraglottitis/epiglottitis)
- Palpable mass (neoplasm)
- Blood in the pharynx or ear (trauma)
• bacterial
  ▪ symptoms: pharyngitis, fever, malaise, headache, abdominal pain, absence of cough
  ▪ signs: fever, tonsillar or pharyngeal erythema/exudate, swollen/tender anterior cervical nodes, halitosis
  ▪ complications: rheumatic fever, glomerulonephritis, suppurative complications (abscess, sinusitis, otitis media, cervical adenitis, pneumonia), meningitis, impetigo

Investigations
• suspected GABHS
  ▪ see Table 34 for approach to diagnosis and management of GABHS
  ▪ gold standard for diagnosis is throat culture
  ▪ rapid test for streptococcal antigen: high specificity (95%) but low sensitivity (50-90%)
  ▪ suspected EBV (infectious mononucleosis)
    ▪ peripheral blood smear, heterophile antibody test (i.e. the latex agglutination assay or "monospot")

Table 34. Modified Centor Score: Approach to Diagnosis and Management of GABHS

<th>28-35%</th>
<th>51-53%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suggested action</td>
<td>NO culture or antibiotic</td>
<td>Culture all, treat with antibiotics only if culture is positive</td>
<td>Culture all, treat with antibiotics on clinical grounds 1, discontinue antibiotics if culture comes back negative</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1Clinical grounds include a high fever or other indicators that the patient is clinically unwell and is presenting early in the course of the illness
Limitations: 1) This score is not applicable to patients less than 3 yr of age
2) If an outbreak or epidemic of illness caused by GABHS is occurring in any community, the score is invalid and should not be used

Management
• viral pharyngitis
  ▪ antibiotics not indicated
  ▪ symptomatic therapy: acetaminophen/NSAIDs for fever and muscle aches, decongestants
• GABHS (see Table 34)
  ▪ antibiotic treatment decreases severity and duration of symptoms, risk of transmission (after 24 h of treatment), and risk of rheumatic fever and suppurative complications
  ▪ incidence of glomerulonephritis is not decreased with antibiotic treatment
  ▪ no increased incidence of rheumatic fever with 48 h delay in antibiotic treatment; if possible, delay antibiotic treatment until culture confirms diagnosis
  ▪ routine F/U and/or post-treatment throat cultures are not required for most patients
  ▪ F/U throat culture only recommended for: patients with history of rheumatic fever, patients of family member(s) with history of acute rheumatic fever, suspected streptococcal carrier
• infectious mononucleosis (EBV)
  ▪ self-limiting course; antibiotics are not indicated
  ▪ symptomatic treatment: acetaminophen/NSAIDs for fever, pharyngitis, malaise
  ▪ avoid heavy physical activity and contact sports for at least one month or until splenomegaly resolves because of risk of splenic rupture
  ▪ if acute airway obstruction, give corticosteroids and consult ENT
Epidemiology
- 50-75% of Canadians report some use of CAM over their lifetime, and only half will disclose this use to their physician
- use is highest in Western provinces and lowest in Atlantic provinces
- more likely to be used by younger patients and those with higher education and income
- examples: chiropractic, acupuncture, massage, naturopathy, homeopathy, traditional Chinese medicine, craniosacral therapy, osteopathy

Herbal Products
- over 50% of Canadians use natural health products (NHPs)
- most commonly used include echinacea, ginseng, ginkgo, garlic, St. John’s Wort, and soy
- relatively few herbal products have been shown to be effective in clinical trials
- many patients believe herbal products are inherently safe and are unaware of potential side effects and interactions with conventional medicines
- all NHPs must be regulated under The Natural Health Products Regulations as of January 1, 2004, including herbal remedies, homeopathic medicines, vitamins, minerals, traditional medicines, probiotics, amino acids, and essential fatty acids (e.g. omega-3)
- always ask patients whether they are taking any herbal product, herbal supplement, or other natural remedy. Further questions may include:
  - are you taking any prescription or non-prescription medications for the same purpose as the herbal product?
  - are you allergic to any plant products?
  - are you pregnant or breastfeeding?
- information resources: National Center for CAM (www.nccam.nih.gov), Health Canada website

St. John’s Wort for Depression
Cochrane DB Syst Rev 2006;2:CD000840
A meta-analysis of 37 trials, including 26 which compared St. John’s Wort with placebo and 14 which compared St. John’s Wort with standard antidepressants. The main outcome measure was the ratio of responders to non-responders, and the main outcome measure for adverse effects was the number of patients dropping out due to adverse experiences. Significant heterogeneity was noted among placebo-controlled trials, but trials were statistically homogeneous for trials comparing St. John’s Wort with antidepressants. For major depression, compared with placebo, the OR for 6 larger trials was 1.15 (95% CI 1.02-1.29) and 5 smaller trials, 2.06 (95% CI 1.65-2.58). Compared with SSRIs and biclycines, the response rates were 0.90 (95% CI 0.85-1.01) and 0.80 (95% CI 0.70-0.88), respectively. Fewer patients on St John’s Wort dropped out due to adverse effects compared to those taking bicallycines (OR 0.25; 95% CI 0.14-0.45), and a similar but non-significant trend was seen when compared with SSRIs (OR 0.60; 95% CI 0.31-1.15). Drawing solid conclusions is difficult given the degree of study heterogeneity and number of conflicting studies.
### Primary Care Models

| Bacterial Conjunctivitis | S. aureus, S. pneumoniae, H. influenzae, M. catarrhalis | Duration is 5-7 d unless otherwise specified |
| | | All doses should be administered while awake |
| | | OTC for adults and children age > 1 yr: |
| | | gramicidin-polymyxin drops (Polysporin® or Optimyxin®): 1 drop q4h |
| | | bacitracin-polymyxin ointment (Polysporin® or Optimyxin®): 1/2 inch qid |
| | | Prescription for adults and children age > 1 yr: |
| | | erythromycin 0.5% ointment: 1/2-1 inch qid |
| | | fusidin 1% drops (children age > 2 yr): 1 drop bid |
| | | sulfacetamide sodium 10% drops: 1-2 drops q2-3h then taper to bid |
| | | Fluoroquinolones preferred for more serious cases, especially suspected Pseudomonas (e.g. contact lens wearers), corneal involvement, or treatment failure: |
| | | ciprofloxacin 0.3% drops: 1-2 drops q2h x 2 d then q4h x 5 d |
| | | ciprofloxacin 0.3% ointment: 1/4 inch bid-tid |
| | | gatifloxacin 0.3% drops: 1-2 drops q2h x 2 d then qid x 5 d |

| Bacterial Conjunctivitis | S. aureus, S. epidermidis, P. acnes, Corynabacteria | Lid hygiene: Mainstay of treatment and works best OD or bid |
| | | Abx ointment: Helpful in short-term of acute phase but resistance rapidly ensues if treatment is prolonged |
| | | 1st line: bacitracin-polymyxin ointment (Polysporin® or Optimyxin®): 1/2 inch qhs |
| | | erythromycin 0.5% ointment: 1/2 inch qhs |
| | | 2nd line: gentamicin 0.3% ointment: 1/2 inch qhs |
| | | tobramycin 0.3% ointment: 1/2 inch qhs |

*All doses are adult doses unless otherwise specified

*This chart is not all-encompassing and is non-inclusive of special exceptions (i.e. pregnancy, poor renal clearance, etc.)

## References
The gastrointestinal tract runs from mouth to anus ("gum to bum").

**Table 1. Summary of Gastrointestinal Tract Structure and Function**

<table>
<thead>
<tr>
<th>Organ</th>
<th>Function</th>
<th>Blood Supply</th>
<th>Innervation</th>
<th>Histology and Structural Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Esophagus</td>
<td>• Muscular tube approximately 25 cm long with a diameter of 2 cm</td>
<td>• Arterial: left gastric artery and left inferior phrenic artery &lt;br&gt; • Venous: &lt;br&gt; - Left gastric vein → portal venous system &lt;br&gt; - Esophageal veins → azygos vein → IVC (systemic)</td>
<td>• Parasympathetic innervation via anterior and posterior gastric nerves (vagal trunks) &lt;br&gt; • Sympathetic innervation via thoracic trunks of the greater splanchnic nerves</td>
<td>• Mucosa: stratified squamous epithelium &lt;br&gt; • Submucosa: connective tissue, lymphocytes, plasma cells, nerve cells &lt;br&gt; • Muscularis propria (muscularis externa): inner circular, outer longitudinal muscle &lt;br&gt; - Upper 1/3: striated muscle &lt;br&gt; - Middle 1/3: transition zone &lt;br&gt; - Lower 1/3: smooth muscle</td>
</tr>
<tr>
<td>Stomach</td>
<td>• Delivers food to intestine for digestion and absorption &lt;br&gt; • Secretes acid, probably to reduce enteric infections/pneumonia; facilitate digestion of protein/iron/B₁₂ &lt;br&gt; • Secretes intrinsic factor to facilitate B₁₂ absorption &lt;br&gt; • Minor contribution to initial protein digestion via pepsin</td>
<td>• Lesser curvature: &lt;br&gt; - Right and left gastric arteries (from celiac trunk) &lt;br&gt; - Greater curvature: &lt;br&gt; - Right and left gastroental (gastronephric) arteries (from gastroduodenal and splenic a. respectively) &lt;br&gt; • Fundus: short and posterior gastric arteries (from the splenic artery)</td>
<td>• Parasympathetic innervation via vagus nerve &lt;br&gt; • Sympathetic innervation via celiac plexus (from T₅-T₉)</td>
<td>5 parts: &lt;br&gt; - Cardia &lt;br&gt; - Fundus &lt;br&gt; - Body &lt;br&gt; - Antrum &lt;br&gt; - Pylorus</td>
</tr>
<tr>
<td>Duodenum</td>
<td>• Modulates enteral pH via secretin → decreased gastric acid secretion, increased bicarbonate secretion &lt;br&gt; • Secretes cholecystokinin (CCK) to stimulate bile secretion &lt;br&gt; • Site of iron absorption</td>
<td>• Branches of celiac artery and superior mesenteric artery (SMA)</td>
<td>• Parasympathetic innervation via vagus nerve &lt;br&gt; • Sympathetic innervation via greater and lesser splanchnic nerves</td>
<td>4 parts &lt;br&gt; - Superior (5 cm) &lt;br&gt; - Descending (7-10 cm) &lt;br&gt; - Horizontal (6-8 cm) &lt;br&gt; - Ascending (5 cm) &lt;br&gt; • 1st part is intraperitoneal; rest is retroperitoneal</td>
</tr>
</tbody>
</table>
### Table 1. Summary of Gastrointestinal Tract Structure and Function (continued)

<table>
<thead>
<tr>
<th>Organ</th>
<th>Function</th>
<th>Blood Supply</th>
<th>Innervation</th>
<th>Histology and Structural Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jejunum</td>
<td>Absorption of salt, water and nutrients (protein, carbohydrates, fat, folic acid, and vit A, B, C, D, E, K)</td>
<td>Superior mesenteric artery</td>
<td>Parasympathetic innervation via fibers of the posterior vagal trunk</td>
<td>Deep red colour&lt;br&gt;2.4 cm in thickness&lt;br&gt;Has a thick and heavy wall&lt;br&gt;Plicae circulars are large, tall and closely packed&lt;br&gt;Has long vasa recta&lt;br&gt;Scant fat in mesentery&lt;br&gt;Scant Peyer’s patches</td>
</tr>
<tr>
<td>Ileum</td>
<td>Absorption of salt, water, nutrients, soluble vitamins (only site of vit B₁₂ absorption) and bile salt (entero-hepatic circulation)</td>
<td>Superior mesenteric artery</td>
<td>Same as jejunum&lt;br&gt;When compared to jejunum: Paler pink colour&lt;br&gt;2.3 cm in thickness&lt;br&gt;Has a thin and light wall&lt;br&gt;Plicae circulars are small and sparse&lt;br&gt;Contains more fat in mesentery than jejunum&lt;br&gt;Has many Peyer’s patches</td>
<td></td>
</tr>
<tr>
<td>Large Bowel</td>
<td>Absorption of water (5-10% of total water)</td>
<td>Branches of superior and inferior mesenteric arteries&lt;br&gt;Rectal blood supply: sigmoid, right pudendal and rectal arteries</td>
<td>Parasympathetic innervation via fibers of the anterior and posterior vagal trunks</td>
<td>Consists of cecum, colon (ascending, transverse, descending, and sigmoid), rectum and anal canal&lt;br&gt;Features include teniae coli, haustra, and omental appendices</td>
</tr>
<tr>
<td>Liver</td>
<td>Glucose homeostasis&lt;br&gt;Plasma protein synthesis&lt;br&gt;Lipid and lipoprotein synthesis&lt;br&gt;Bile acid synthesis and secretion&lt;br&gt;Vitamin A, D, E, K, B₁₂, storage&lt;br&gt;Biotransformation, detoxification&lt;br&gt;Excretion of compounds</td>
<td>2 sources&lt;br&gt;Portal vein (75-80%)&lt;br&gt;Hepatic artery (20-25%)</td>
<td>Sympathetic innervation via fibers of the celiac plexus&lt;br&gt;Parasympathetic innervation via fibers of the anterior and posterior vagal trunks</td>
<td>Largest internal organ&lt;br&gt;Composed of 4 lobes (left, right, caudate, quadrate) and divided into 8 segments</td>
</tr>
<tr>
<td>Biliary Tract</td>
<td>Gallbladder functions to store and release bile that is produced in the liver&lt;br&gt;Bile is used to emulsify fat and is composed of cholesterol, lecithin, bile acids and bilirubin&lt;br&gt;CCK stimulates gallbladder emptying while trypsin and chymotrypsin inhibit bile release</td>
<td>Cystic artery</td>
<td>Parasympathetic innervation via vagus nerve&lt;br&gt;Sympathetic and visceral innervation via celiac nerve plexus&lt;br&gt;Somatic afferent fibers via right phrenic nerve</td>
<td>Consists of the hepatic ducts (intrahepatic, left, right and common), gallbladder, cystic duct, common bile duct and ampulla of Vater</td>
</tr>
<tr>
<td>Pancreas</td>
<td>Endocrine function: islets of Langerhans produce glucagon, insulin and somatostatin (from the α, β and δ cells, respectively)&lt;br&gt;Exocrine function: digestive enzymes are produced including amylase, lipase, trypsin, chymotrypsin and carboxypeptidase</td>
<td>Anterior superior pancreaticoduodenal artery (from the celiac trunk)&lt;br&gt;Anterior inferior pancreaticoduodenal artery (from the superior mesenteric artery)&lt;br&gt;Dorsal pancreatic artery (from the splenic artery)&lt;br&gt;Pancreatic veins drain into the portal, splenic and superior mesenteric veins</td>
<td>Parasympathetic innervation via vagus nerve&lt;br&gt;Sympathetic innervation via abdominopelvic splanchnic nerves</td>
<td>4 parts of pancreas: head (includes uncinate process), neck, body, and tail&lt;br&gt;(Major) Pancreatic duct connecting to common bile duct prior to ampulla of Vater&lt;br&gt;Accessory pancreatic duct connecting directly to duodenum</td>
</tr>
</tbody>
</table>

### Visualizing the GI Tract

- see also Medical Imaging, MI10

**Esophagus, Stomach, Duodenum**

- oesophagogastroduodenoscopy (OGD): best visualization of mucosa; also allows for therapeutic intervention (banding varices, cauterizing/clipping/injecting bleeding ulcers, and dilating esophageal strictures)
- consider barium swallow first if dysphagia, decreased level of consciousness (increases risk of aspiration), inability to cooperate (increases risk of pharyngeal trauma during intubation)
- endotracheal intubation first if massive upper GI bleed, acidosis or unable to protect airway

---

**Retroperitoneal Structures**

- SAD PUCKER
  - Suprarenal glands (adrenal glands)
  - Aorta/IVC
  - Duodenum (second to fourth segments)
  - Pancreas (tail is intraperitoneal)
  - Ureters
  - Colon (only the ascending and descending branches)
  - Kidneys
  - Esophagus
  - Rectum

**Only the ileum (not jejunum), can absorb vitamin B₁₂ and bile acids.**

---
Small Bowel
- most difficult to visualize, especially if mucosal detail is needed
- CT enterography more accurate than small bowel follow through, but both have low sensitivity
- MRI enteroclysis increasingly available (use enteroclysis if dilation of the small bowel might improve sensitivity, such as diverticulosis, or if stricture suspected)
- “double balloon” enteroscopy (enteroscope with balloons proximally and distally to propel endoscope into jejunum from mouth or into ileum from anus) may be most sensitive but currently available only in selected centres; technically demanding
- wireless endoscopy capsule (26 x 11 mm capsule is swallowed, transmits images to a computer; contraindicated in bowel obstruction) is also accurate in diagnosis but unable to provide any therapeutic intervention

Colon and Terminal Ileum
- colonoscopy, with biopsy if required; contraindicated in perforation, acute diverticulitis and severe colitis (increased risk of perforation)
- CT colonoscopy (“virtual colonoscopy”) more accurate in diagnosing diverticulosis, extrinsic pressure on colon (e.g. ovarian cancer compressing sigmoid colon) and fistulae; increasing evidence for use in colorectal cancer screening

Pancreatic/Biliary Duct
- MRCP almost as sensitive as ERCP in determining if bile duct obstruction present, but less accurate in determining cause of obstruction (tumour, stone, stricture)
- ERCP if endoscopic draining necessary, strong suspicion of stone, obstruction requiring stenting, or if tissue sampling required

Differential Diagnosis of Common Presenting Complaints

Esophagus

Gastroesophageal Reflux Disease (GERD)

Definition
- condition in which the stomach contents (solid or liquid) leak backwards from the stomach into the esophagus (the tube from the mouth to the stomach)

Etiology
- inappropriate transient relaxations of lower esophageal sphincter (LES) – most common
- low basal LES tone (especially in scleroderma)
- contributing factors include: delayed esophageal clearance, delayed gastric emptying, increased intra-abdominal pressure
- acid hypersecretion (rare): Zollinger-Ellison syndrome (gastrin-secreting tumour)
- hiatus hernia worsens reflux, does not cause it (see General Surgery, GS22)

Clinical Features
- “heartburn” (pyrosis) and acid regurgitation (together are 80% sensitive and specific for reflux) ± sour regurgitation, water brash, sensation of a lump in the throat (bolus sensation) and frequent belching
- non-esophageal symptoms (see below) are increasingly recognized of being poor predictors of reflux

Investigations
- usually a clinical diagnosis based on symptom history and relief following a trial of pharmacotherapy (proton pump inhibitor (PPI): symptom relief 80% sensitive for reflux)
  - absolute indications:
    - heartburn accompanied by red-flags (bleeding, weight loss, etc.)
    - persistent reflux symptoms or previous severe erosive esophagitis after therapeutic trial of 4-8 wk of PPI 2x daily
    - history of esophageal stricture with persistent dysphagia
  - repeat endoscopy indicated only if known Barrett’s (or recurrence of symptoms) because future likelihood of Barrett’s and esophagitis is minimal if the first endoscopy is normal

Figure 2. Signs and symptoms of GERD

Gastroesophageal Reflux Disease (GERD)

Non-erosive reflux disease (NERD)
- Normal esophagus
- Aim for symptom relief only; proton pump inhibitor PRN

Esophagitis
- Normal esophagus
- Esophageal inflammation
- Aim to heal inflammation; proton pump inhibitor indefinitely or surgical fundoplication

Esophageal damage from reflux is most severe at first gastroscopy, therefore necessary only once for patients with NERD.
• esophageal manometry (study of esophageal motility)
  ▪ may be done to diagnose abnormal peristalsis and/or decreased LES tone, but cannot detect presence of reflux; indicated before surgical fundoplication to ensure esophageal functional
  ▪ surgical fundoplication (wrapping of gastric fundus around the lower end of the esophagus) more likely to be successful if lower esophageal pressure is diminished; less likely to be successful if abnormal peristalsis
• 24-h pH monitoring: most accurate test, but rarely required or performed
  ▪ most useful if PPIs do not improve symptoms

Management
• PPIs are the most effective therapy and usually need to be continued as maintenance therapy
• on-demand: antacids (Mg(OH)₂, Al(OH)₃, alginate), H₂-blockers or PPIs can be used for NERD
• diet helps symptoms, not the disease; avoid alcohol, coffee, spices, tomatoes and citrus juices
• only beneficial lifestyle changes are weight loss (if obese) and elevating the head of bed (if nocturnal symptoms)
• dyspepsia may recur if therapy is discontinued

Complications
• esophageal stricture disease – scarring can lead to dysphagia (solids)
• ulcer
• bleeding
• Barrett’s esophagus (see below) and esophageal adenocarcinoma – gastroscopy is recommended for patients with chronic GERD or symptoms suggestive of complicated disease (e.g. anorexia, weight loss, bleeding, dysphagia)

Barrett’s Esophagus

Definition
• metaplasia of normal squamous esophageal epithelium to abnormal columnar epithelium containing intestinal metaplasia

Etiology
• thought to be acquired via long-standing GERD and consequent damage to squamous epithelium

Epidemiology
• in North America and Western Europe, 0.5-2.0% of adults are thought to have Barrett’s esophagus
• up to 10% of GERD patients will have already developed BE by the time they seek medical attention
• more common in males, age >50, Caucasians, smokers, overweight, hiatus hernia and long history of reflux symptoms

Pathophysiology
• endoscopy shows erythematous epithelium in distal esophagus; diagnosis of BE relies on biopsy demonstrating the presence of specialized intestinal epithelium of any length within the esophagus
• BE predisposes to premalignant changes in abnormal columnar epithelium, characterized as low- or high-grade dysplasia

Significance
• rate of malignant transformation is approximately 0.12% per year for all BE patients prior to dysplasia
• risk of malignant transformation in high-grade dysplasia is significantly higher; studies have reported a 32-59% transformation rate over 5-8 yr of surveillance
• increased gastric acid secretion is more frequently associated with Barrett’s esophagus as opposed to reflux alone

Management
• acid suppressive therapy with high-dose PPI indefinitely (or surgical fundoplication)
• endoscopy every 3 yr if no dysplasia
• high grade dysplasia: regular and frequent surveillance with intensive biopsy, endoscopic ablation/resection, or esophagectomy produce similar outcomes; however, evidence increasingly favouring endoscopic ablation with mucosal resection or radiofrequency ablation
• if low grade dysplasia, both surveillance and endoscopic ablation/resection are satisfactory options

Complications
• esophageal stricture disease – scarring can lead to dysphagia (solids)
• ulcer
• bleeding
• Barrett’s esophagus (see below) and esophageal adenocarcinoma – gastroscopy is recommended for patients with chronic GERD or symptoms suggestive of complicated disease (e.g. anorexia, weight loss, bleeding, dysphagia)
Eosinophilic Esophagitis

Definition
- inflammatory condition with prominence of eosinophils on esophageal biopsy
- most commonly found in children, but increasingly recognized in adults

Etiology
- unknown; may be an "allergic" disorder in children
- cytokines cause edema and fibrosis

Clinical Features
- odynophagia or dysphagia (solids); history often dates back to childhood
- first presentation may be to ER with food bolus impaction
- allergies common

Investigations
- endoscopy may reveal multiple rings or "crepe-paper" appearance
- biopsy showing increased eosinophils is necessary to confirm diagnosis

Management
- corticosteroid (e.g. fluticasone) spray (swallowed not inhaled)
- budesonide in a matrix to increase contact time with esophageal mucosa
- leukotriene B4 inhibitors (e.g. Montelukast)
- rule out food allergies: elimination diets have been an effective therapy in children

Complications
- increased risk of perforation with endoscopic dilatation procedures

Dysphagia

Definition
- difficulty swallowing, sensation of food "sticking" after swallowing

Esophageal Motor Disorders

Symptoms
- dysphagia with solids and liquids
- chest pain (in some disorders)

Diagnosis
- motility study (esophageal manometry)
- barium swallow sometimes helpful

Causes (Table 3)
- idiopathic
- achalasia (painless)
- scleroderma (painless)
- diabetes
- diffuse esophageal spasm (DES); rare and can be difficult to diagnose due to intermittent presentation

Key Questions in Dysphagia
- Difficulty in starting swallowing?
- Associated symptoms? (regurgitation, change in voice pitch, weight loss)
- Solids, liquids or both?
- Intermittent or progressive?
- History of heartburn?
- Change in eating habits/diet?

Dysphagia = Difficulty in swallowing
Odynophagia = Pain on swallowing
Table 3. Esophageal Motor Disorders

<td></td>
</tr>
<tr>
<td>Treatment</td>
<td>• Dilatation of LES with balloon, ≥ GERD prophylaxis, 50% good response, can repeat, risk of perforation (5%)</td>
<td>• Medical: aggressive GERD therapy (PPIs bid)</td>
<td>• Reassurance not cardiac pain</td>
</tr>
<tr>
<td></td>
<td>• Injection of botulinum toxin into LES (temporary)</td>
<td>• Surgery: anti-reflux surgery (gastroplasty, last resort)</td>
<td>• Medical: nitrates, calcium channel blockers, anticholinergics have variable benefit</td>
</tr>
<tr>
<td></td>
<td>• Surgery (myomectomy)</td>
<td></td>
<td>• Surgical: long esophageal myotomy if unresponsive to above treatment (rarely helpful); balloon dilatation</td>
</tr>
</tbody>
</table>

**Esophageal Diverticula**

**Definition**
- outpouchings of one or more layers of the esophageal tract

**Clinical Features**
- commonly associated with motility disorders
- dysphagia, regurgitation, retrosternal pain, intermittent vomiting, may be asymptomatic

**Classification**
- classified according to location
  - pharyngoesophageal (Zenker’s) diverticulum
  - most frequent form of esophageal diverticulum
  - posterior pharyngeal outpouching most often on the left side, above cricopharyngeal muscle and below the inferior pharyngeal constrictor muscle
  - symptoms: dysphagia, regurgitation of undigested food, halitosis
  - treatment: endoscopic or surgical myotomy of cricopharyngeal muscle ± surgical excision of sac
- mid-esophageal diverticulum
  - secondary to mediastinal inflammation, motor disorders
  - usually asymptomatic; no treatment required
- just proximal to LES (pulsatile type)
  - usually associated with motor disorders
  - usually asymptomatic; no treatment required

**Peptic Stricture (from Esophagitis)**
- presents as dysphagia alongside a long history of reflux symptoms, but reflux symptoms may disappear as stricture develops
- diagnosed with endoscopy or barium study if endoscopy contraindicated or unavailable

**Treatment**
- endoscopic dilatation and indefinite PPI
- anti-reflux surgery if above treatment unsuccessful
Esophageal Carcinoma

- see General Surgery, GS14

Webs and Rings

- web = partial occlusion (upper esophagus)
- ring = circumferential narrowing (lower esophagus)

Clinical Features
- asymptomatic with lumen diameter >12 mm, provided peristalsis is normal
- dysphagia with large food boluses
- Plummer-Vinson (or Patterson-Kelly syndrome)
  - upper esophageal web with iron deficiency, plus cheilosis (dry scaling and fissuring of the lips) and koilonychia (concave outer nail surface)
  - usually in middle-aged females (>40 yr)
  - elevated risk of hypopharyngeal carcinoma
- Schatzki's ring
  - mucosal ring at squamo-columnar junction above a hiatus hernia
  - causes intermittent dysphagia with solids
  - treatment involves disrupting ring with endoscopic bougie

Infectious Esophagitis

Definition
- severe mucosal inflammation and ulceration as a result of a viral or a fungal infection

Risk Factors
- diabetes
- chemotherapeutic agents
- immunocompromised states

Symptoms
- characteristically odynophagia, less often dysphagia
- diagnosis is via endoscopic visualization and biopsy

Appearance
- Candida (most common): whitish-yellow plaques without visible ulceration or inflammation
- Herpes (second most common), CMV: focal ulcers

Treatment
- Candida: nystatin swish and swallow, ketoconazole, fluconazole
- Herpes: often self-limiting; acyclovir, valacyclovir, famciclovir
- CMV: IV gancyclovir, famciclovir or oral valganciclovir

Stomach and Duodenum

Dyspepsia

Definition
- intermittent epigastric discomfort, characteristically develops after eating

History and Physical
- history: most important are age, associated symptoms (such as weight loss and vomiting), and drugs (especially NSAIDs)
- physical examination: adenopathy, abdominal mass/organomegaly, Carnett's sign (if pain is due to abdominal wall muscle problem then the pain will increase during muscle contraction, such as during a sit-up)

Investigations
- laboratory: usual (CBC, liver enzymes, glucose, Cr, etc.) plus amylase, albumin
- consider trial of empiric anti-secretory drug therapy, non-invasive testing for H. pylori infection, endoscopy, barium radiography

The most common cause of dyspepsia is functional (idiopathic) dyspepsia. “Neither clinical impression nor computer models can adequately distinguish between organic disease and functional disease in patients referred for endoscopic evaluation of dyspepsia.”

JAMA 2006;295:1566-1576
Gastric Acid Secretion

Stomach
- primary function is mechanical grinding of food facilitating early enzymatic digestion into chyme and propulsion into duodenum

Table 4. Cells of the Gastric Mucosa

Gastritis

Definition
- defined histologically: inflammation of the stomach mucosa

Etiology
- some causative agents may play a role in more than one type of gastritis and an individual patient may have histopathological evidence of more than one type of gastritis

Table 5. Updated Sydney Classification of Gastritis

<table>
<thead>

</tr>
</tbody>
</table>

*Most common causes
Clinical Features
- non-erosive gastritis is asymptomatic (except in certain rare causes like Crohn's Disease); difficult to diagnose clinically or endoscopically
- erosive gastritis can cause bleeding (pain only if progresses to ulcers – rare); can be seen endoscopically

Management
- determined by etiology (see H. Pylori section, G13, NSAID section, G14 and Stress-Induced Ulceration section, G14)
- non-pharmacological: avoidance of mucosal irritants such as alcohol, NSAIDs and foods that trigger symptoms

Peptic Ulcer Disease (PUD)

Definition
- focal defects in the mucosal that penetrate the muscularis mucosal layer results in scarring (defects superficial to the muscularis mucosa have erosions and no scarring)
- peptic ulcer disease includes defects located in the stomach (gastric ulcers) and duodenum (duodenal ulcers)

Etiology

Table 6. Etiology of Peptic Ulcer Disease

<table>
<thead>
<tr>

<tr>
<td>Idiopathic</td>
<td>15%</td>
<td>10%</td>
</tr>
</tbody>
</table>

- NSAID negative, H. pylori negative ulcers becoming more commonly recognized
- others: CMV, ischemic, idiopathic
- alcohol: damages gastric mucosa but rarely causes ulcers
- peptic ulcer associated with tobacco, cirrhosis of liver, COPD and chronic renal failure

Clinical Features
- dyspepsia: most common presenting symptom
  - only 20% of patients with dyspepsia have ulcers, while most have functional disease
- may present with complications
  - bleeding 10% (severe if from gastroduodenal artery) (see Bleeding Peptic Ulcer, G13)
  - perforation 2% (usually anterior ulcers)
  - gastric outlet obstruction 2%
  - penetration (posterior) 2%; may also cause pancreatitis
- duodenal ulcers: 6 classical features, but history alone cannot distinguish from functional dyspepsia
  - epigastric pain; may localize to tip of xiphoid
  - burning
  - develops 1-3 h after meals
  - relieved by eating and antacids
  - interrupts sleep
  - periodicity (tends to occur in clusters over wk with subsequent periods of remission)
- gastric ulcers: more atypical symptoms; a biopsy is necessary to exclude malignancy

Investigations
- endoscopy (most accurate)
- upper GI series
- H. pylori tests (see Table 7)
- fasting serum gastrin measurement if Zollinger-Ellison (ZE) syndrome suspected

Treatment
- specific management depends on etiology; (see H. Pylori section, G13, NSAID section, G14 and Stress-Induced Ulceration section, G14)
- eradicate H. pylori if present, chief advantage is to lower ulcer recurrence rate
- stop NSAIDs if possible
- start PPI: inhibits parietal cell H^+/K^-ATPase pump which secretes acid
  - heals most ulcers, even if NSAIDs are continued
- other meds (e.g. histamine H2-antagonists) less effective
- discontinue tobacco
- no diet modifications required but some people have fewer symptoms if they avoid caffeine, alcohol and spices
Management of Bleeding Peptic Ulcers
- OGD to explore upper GI tract (see Figure 6)
- establish risk of rebleeding/continuous bleed
  - clinical risk factors: increased age (>60), bleeding diathesis, history of PUD, comorbid disease, hemodynamically unstable
  - endoscopic signs of recurrent bleeding (active bleeding, visible vessel, clot, red spot) more predictive than clinical risk factors
  - if high risk, consider ICU admission

Figure 6. Approach to management of suspected bleeding peptic ulcer
Adapted from: Gralnek I, Barkun A, Bardou M. Management of acute bleeding from a peptic ulcer. NEJM 2008;359:928-937

**H. pylori-Induced Peptic Ulceration**

Pathophysiology
- *H. pylori*: Gram-negative flagellated rod that resides on but does not invade the gastric mucosa
- acid secreted by parietal cells (stimulated by vagal acetylcholine, gastrin, histamine) necessary for most ulcers
- mucosal defenses moderated by PGE2 and blood flow, mucus, etc.
- theories of how *H. pylori* causes ulcers: none satisfactory, but pattern of colonization correlates with outcome
  - gastritis only in antrum (15% of patients), high gastric acid, associated with peptic ulcer, may progress to gastric metaplasia of duodenum where ulcer forms
  - gastritis throughout stomach (“pangastritis” – 85% of patients), low gastric acid, associated with cancer

Epidemiology
- *H. pylori* is found in about 20% of all Canadians
  - highest prevalence in those raised during 1930s
  - infection most commonly acquired in childhood, presumably by fecal-oral route
  - high prevalence in developing countries, low socioeconomic status (poor sanitation and overcrowding)

Outcome
- gastritis (non-erosive) in 100% of patients but asymptomatic
- peptic ulcer in 15% of patients
- gastric malignancy [gastric carcinoma and mucosal associated lymphomatous tissue (MALT) lymphoma in 0.5% of patients]
- most are asymptomatic but still worthwhile eradicating to lower future risk of peptic ulcer/gastric malignancy and prevent spread to others (mostly children <5 yr of age)

</table>

Treatment: *H. pylori* Eradication

- **triple therapy for 7-14 d (Hp-Pac®):** PPI bid (e.g. lansoprazole 30 mg bid) + amoxicillin 1 g bid + clarithromycin 500 mg bid
  - 80% success rate
- **quadruple therapy for 10-14 d:** PPI bid + bismuth 525 mg qid + tetracycline 500 mg qid + metronidazole 250 mg qid
  - only recommended as first line therapy if resistance to clarithromycin or metronidazole is high, or in patients with recent or repeated exposure to these drugs
  - levofloxacin can replace metronidazole or tetracycline
- **sequential therapy**
  - days 1-5: PPI bid + amoxicillin 1 g bid
  - days 6-10: PPI bid + clarithromycin 500 mg bid + tinidazole 500 mg bid
- 5-15% of cases are resistant to all known therapies

**NSAID-Induced Ulceration**

- NSAID use causes gastric mucosal petechiae in virtually all, erosions in most, ulcers in some (25%)—erosions bleed, but usually only ulcers cause significant clinical problems
- most NSAID ulcers are clinically silent: dyspepsia is as common in patients with ulcers as in patients without ulcers; NSAID-induced ulcers characteristically present with complications (bleeding, perforation, obstruction)
- NSAIDs more commonly cause gastric ulcers than duodenal ulcers
- may exacerbate underlying duodenal ulcer disease

**Pathophysiology**

- direct: erosions/petechiae – are due to local (direct) effect of drug on gastric mucosa
- indirect: systemic NSAID effect (intravenous NSAID causes ulcers, but not erosions), inhibits mucosal cyclooxygenase, leading to decreased synthesis of protective prostaglandins, thus leading to ulcers

**Risk Factors For NSAID Causing Peptic Ulcer**

- previous peptic ulcers/UGIB
- age
- high dose of NSAID/multiple NSAIDs being taken
- concomitant corticosteroid use
- concomitant cardiovascular disease/other significant diseases

**Treatment**

- prophylactic cytoprotective therapy with a PPI is recommended if any of the above risk factors exist concomitantly with ASA/NSAID use
- lower NSAID dose or stop all together and replace with acetaminophen
- combine NSAID with PPI or misoprostol
- enteric coating of Aspirin® (ECASA) provides minor benefit since this decreases incidence of erosion, not incidence of ulceration

**Stress-Induced Ulceration**

**Definition**

- ulceration or erosion in the upper GI tract of ill patients, usually in ICU
- lesions most commonly in fundus of stomach

**Pathophysiology**

- unclear: likely involves ischemia; may be caused by CNS disease, acid hypersecretion, Cushing ulcers
- physiological stress (e.g. fever, severe illness, complex post-op course) causes ulcers and erosions
Risk Factors
- mechanical ventilation
- anti-coagulation
- multi-organ failure
- septicemia
- severe surgery/trauma
- CNS injury ("Cushing's ulcers")
- burns involving more than 35% of body surface

Clinical Features
- UGIB (see Upper Gastrointestinal Bleeding, G25)
- painless

Treatment
- prophylaxis with gastric acid suppressants (H$_2$-blockers or PPI) decreases risk of UGIB, but may increase risk of pneumonia
- treatment same as for bleeding peptic ulcer but often less successful

Gastric Carcinoma
- see General Surgery, GS18

Small and Large Bowel

Classification of Diarrhea

Definition
- clinically: diarrhea defined as stools that are looser and/or more frequent than normal; physiologically: 24 h stool weight >200 g (less useful clinically)

Classification
- acute vs. chronic
- small volume (tablespoons of stool; typical of colonic diseases) versus large volume (>1/2 cup stool; typical of small bowel diseases)
- watery (bowel disease) vs. steatorrhea
- secretory (diarrhea persists with fasting) vs. osmotic (diarrhea stops with fasting)

Acute Diarrhea

Definition
- passage of frequent unformed stools for <14 d

Etiology
- most commonly due to infections
- most infections are self-limiting and resolve within 7 d

Risk Factors
- food (seafood, chicken, turkey, eggs, beef)
- medications: antibiotics, laxatives
- others: high risk sexual activity, infectious outbreaks, family history (IBD)

Classification
- broadly divided and classified into inflammatory and non-inflammatory diarrhea
- mechanisms:
  - stimulation of intestinal water secretion and inhibition of water absorption (i.e. secretory problem)
  - in inflammatory diarrhea, organisms and cytotoxins invade mucosa, killing mucosal cells, further perpetuating the diarrhea

<table>

Useful Questions in Acute Diarrhea
- Those Fads Wilt
- Travel
- Homosexual contacts
- Outbreaks
- Seafood
- Extra-intestinal signs of IBD
- Family history
- Antibiotics
- Diet
- Steatorrhea
- Weight loss
- Immunosuppressed
- Laxatives
- Tumour history

Infectious Causes of Inflammatory Diarrhea
- "Your Stool Smells Extremely Crappy"
- Yersinia
- Shigella
- Salmonella
- E. coli (EHEC 0157:H7), E. histolytica
- Campylobacter, C. difficile
Table 8. Classification of Acute Diarrhea (continued)

</tr>
<tr>
<td></td>
<td>Can progress to life-threatening megacolon, perforation, hemorrhage</td>
<td>Chief life-threatening problem is electrolyte disturbances/ fluid depletion</td>
</tr>
<tr>
<td></td>
<td>Antibiotics may benefit</td>
<td>Antibiotics unlikely to be helpful</td>
</tr>
</tbody>
</table>

Investigations
- stool cultures/microscopy (C&S/O&P) are required only if diarrhea is inflammatory, severe, or for epidemiological purposes (day care worker, nursing home resident, etc.)
  - C&S only tests Campylobacter, Salmonella, Shigella, E. Coli
  - other organisms must be ordered separately
- flexible sigmoidoscopy: useful if inflammatory diarrhea suspected
  - biopsies are the most useful method of distinguishing idiopathic IBD (Crohn's disease and ulcerative colitis) from infectious colitis or acute self-limited colitis
- C. difficile toxin: indicated when recent/remote antibiotic use, hospitalization, nursing home or recent chemotherapy

Treatment
- fluid and electrolyte replacement orally in most cases, intravenous if severe extremes of age/coma
- anti-diarrheals
  - antimitoty agents: diphenoxylate, loperamide (Imodium®); contraindicated in mucosal inflammation
    - side effects: abdominal cramps, toxic megacolon
  - absorbants: kaolin/pectin (Kaopectate®), methylcellulose, activated attapulgite
    - act by absorbing intestinal toxins/micro-organisms, or by coating intestinal mucosa
    - much less effective than antimitoty agents
  - modifiers of fluid transport: bismuth subsalicylate (Pepto-Bismol®) may be helpful
- antibiotics: rarely indicated
  - risks
    - prolonged excretion of enteric pathogen (especially Salmonella)
    - drug side effects (including C. difficile infection)
    - development of resistant strains
    - renal failure/hemolyis (enterohemorrhagic E. Coli O157:H7)
- indications for antimicrobial agents in acute diarrhea:
  - septicemia
  - prolonged fever with fecal blood or leukocytes
  - clearly indicated: Shigella, V. cholerae, C. difficile, traveller’s diarrhea [enterotoxigenic E. coli (ETEC)], Giardia, Entamoeba histolytica, Cyclospora
  - situational: Salmonella, Campylobacter, Yersinia, non-enterotoxigenic E. coli
  - Salmonella: always treat Salmonella typhi (typhoid or enteric fever); treat other Salmonella only if there is underlying immunodeficiency, hemolytic anemia, extremes of age, aneurysms, prosthetic valve grafts/joints, sickle cell disease

Traveller’s Diarrhea
- see Infectious Diseases, ID14

Chronic Diarrhea

Definition
- passage of frequent unformed stool for >14 d
- approach is similar to that of acute diarrhea except that the majority of cases are non-infectious

Etiology/Classification
- see Differential Diagnosis of Common Presenting Complaints, G4

Investigations
- guided by history
- stool analysis for: C. difficile toxin, C&S, O&P ± fecal fat, WBC.
- blood for: CBC, electrolytes, CRP, TSH, celiac serology (anti-tTG, protein electrophoresis, IgA)
- colonoscopy and ileoscopy with biopsy
- upper GI endoscopy with duodenal biopsy
- wireless small bowel endoscopy capsule (last resort – very costly)
- trial of lactose free diet
  - caveat: may delay diagnosis of IBD and celiac disease
Maldigestion and Malabsorption

Definition
- **maldigestion**: inability to break down large molecules in the lumen of the intestine into their component small molecules
- **malabsorption**: inability to transport molecules across the intestinal mucosa into circulation
- **malassimilation**: encompasses both maldigestion and malabsorption

Etiology
- **maldigestion**
  - inadequate mixing of food with enzymes (e.g. post-gastrectomy)
  - pancreatic exocrine deficiency
  - primary diseases of the pancreas (e.g. cystic fibrosis, pancreatitis, cancer)
  - bile salt deficiency
    - terminal ileal disease (impairment recycling), bacterial overgrowth (deconjugation of bile salts), rarely liver disease (cholestasis)
  - specific enzyme deficiencies (e.g. lactase)
- **malabsorption**
  - inadequate absorptive surface
    - infections/infestations (e.g. Whipple’s disease, Giardia)
    - immunologic or allergic injury (e.g. celiac disease)
    - infiltration (e.g. lymphoma, amyloidosis)
    - fibrosis (e.g. systemic sclerosis, radiation enteritis)
    - bowel resection
    - extensive Crohn’s disease
  - drug-induced
    - cholestyramine, ethanol, neomycin, tetracycline and other antibiotics
  - endocrine
    - diabetes (complex pathogenesis)

Clinical Features
- symptoms usually vague unless disease is severe
- weight loss, diarrhea, steatorrhea, weakness, fatigue
- manifestations of malabsorption/deficiency (see Table 9)

</tbody>
</table>

* Calcium malabsorption more commonly causes decreased bone density rather than hypocalcemia because serum calcium levels are protected by leaching calcium from the bone
Investigations
- transglutaminase serology/protein electrophoresis and abdominal imaging are most useful because celiac disease and chronic pancreatitis are the two most common causes of steatorrhea
- 72 h stool collection (weight, fat content) documents steatorrhea
- serum carotene, folate, Ca\(^{2+}\), Mg\(^{2+}\), vitamin B\(_{12}\), albumin, ferritin, serum iron solution, INR/PTT
- stool fat globules on fecal smear stained with Sudan (rarely used)
- other tests specific for etiology (e.g. CT scan/MRI to visualize pancreas)
- trial of therapy with pancreatic enzymes

Treatment
- dependent on underlying etiology

Celiac Disease (Gluten Enteropathy/Sprue)

Definition
- abnormal small intestine mucosa due to intestinal reaction to gliadin, a component of gluten found in cereal grains

Etiology
- only autoimmune disease in which antigen (α-gliadin) is recognized
- associated with other autoimmune diseases, especially thyroid disease
- gluten, a protein in cereal grains, broken down to gliadin, is toxic factor
- HLA-DQ2 (chromosome 6) found in 80-90% of patients compared with 20% in general population; also associated with HLA-DQ8

Epidemiology
- more common in women
- family history: 15% of first-degree relatives
- may present any time from infancy (when cereals introduced) to elderly
- peak presentation in infancy

Clinical Features
- classically: diarrhea, weight loss, anemia, symptoms of vitamin/mineral deficiency, failure to thrive; now more commonly bloating, gas, iron deficiency
- improves with gluten-free diet, deteriorates when gluten reintroduced
- disease is usually most severe in proximal bowel
  - thus iron, calcium and folic acid deficiency more common than vitamin B\(_{12}\) deficiency
- gluten enteropathy may be associated with dermatitis herpetiformis skin eruption, epilepsy, myopathy, depression, paranoia, infertility, bone fractures/metabolic bone disease

Investigations
- small bowel mucosal biopsy (usually duodenum) is diagnostic with:
  - villous atrophy and crypt hyperplasia
  - increased number of plasma cells and lymphocytes in lamina propria
  - increased intraepithelial lymphocytes
  - villous atrophy also seen in small bowel overgrowth, Crohn's, lymphoma, Giardia, HIV
- consider CT enterography to visualize small bowel to rule out lymphoma
- evidence of malabsorption (localized or generalized)
  - steatorrhea
  - low levels of ferritin/iron saturation, Ca\(^{2+}\), Fe, albumin, cholesterol, carotene, B\(_{12}\) absorption
- improvement with a gluten-free diet; should not be started before anti-tTG and biopsy
- serological tests
  - serum anti-tTG antibody, IgA, is 90-98% sensitive, 94-97% specific
  - IgA deficient patients have false-negative anti-tTG
  - thus measure serum IgA concomitantly (via serum protein electrophoresis)
  - fecal fat >7%

Treatment
- dietary counselling
  - gluten free diet: avoid barley, rye, wheat
    - oats allowed if not contaminated by other grains
  - rice and corn flour are acceptable
  - iron, folate supplementation (with supplementation of other vitamins as needed)
- if poor response to diet change, consider:
  - alternate diagnosis
  - non-adherence to gluten-free diet
  - concurrent disease (e.g. microscopic colitis, pancreatic insufficiency)

Gluten found in “BROW”
Barley
Rye
Oats (controversial)
Wheat

Gluten Microchallenge with Wheat-based Starch Hydrolysates in Celiac Disease Patients
Aliment Pharm Therap 2008;28:1240-1248
Study: Randomized, placebo-controlled, prospective study with 24 wk follow-up.
Participants: 90 patients with celiac disease in remission.
Intervention: Patients either received glucose syrups, maltodextrins or placebo.
Primary Outcome: Small bowel mucosal morphology and inflammation, symptoms, celiac serology and malabsorption.
Results: There were no significant differences between the intervention and control group in small-bowel morphology and inflammation, gastrointestinal symptoms, serology or malabsorption parameters.
Conclusion: Celiac patients can safely continue to consume wheat-based starch hydrolysates, glucose syrups and maltodextrins.
- development of intestinal (enteropathy-associated T-cell) lymphoma (abdominal pain, weight loss, palpable mass)
- development of diffuse intestinal ulceration, characterized by aberrant intraepithelial T-cell population (precursor to lymphoma)

**Prognosis**
- associated with increased risk of lymphoma, carcinoma (e.g. small bowel and colon)
- risk of malignancy may be lowered by dietary gluten restriction

---

**Inflammatory Bowel Disease (IBD)**

**Definition**
- Crohn’s disease, ulcerative colitis, indeterminate colitis

**Pathophysiology**
- poorly understood
- sustained response of the immune system, perhaps to enteric flora in a genetically predisposed individual
- current hypothesis: lack of appropriate down-regulation of immune responsiveness

**Genetics**
- increased risk of both UC and CD in relatives of patients with either disease, especially siblings, early onset disease
  - familial risk greater if proband has CD rather than UC
- likely polygenomic pattern: 9 gene loci described to be associated
- CARD15/NOD2 gene mutation associated with CD (relative risk in heterozygote is 3, in homozygote is 40), especially Ashkenazi Jews, early onset disease, ileal involvement, fistulizing and stenotic disease
  - CARD15 gene product modulates NFκB, which is required for the innate immune response to microbial pathogens, best expressed in monocytes-macrophages

**Clinical Features**

Crohn’s Disease (CD)

Definition
- chronic transmural inflammatory disorder potentially affecting the entire gut from mouth to perianal region (“gum to bum”)

Epidemiology
- incidence 1-6/100,000; prevalence 10-100/100,000
- bimodal: onset before 30 yr, second smaller peak age 60; M=F
- incidence of Crohn’s increasing (relative to UC) especially in young females
- more common in Caucasians, Ashkenazi Jews
  - risk in Asians increases with move to Western countries
- smoking incidence in Crohn’s patients is higher than general population

Clinical Features
- natural history unpredictable; young age, perianal disease, and need for corticosteroids have been associated with poor prognosis, but associations are not strong enough to guide clinical decisions
- most often presents as recurrent episodes of abdominal cramps, diarrhea and weight loss
- most common location: ileum + ascending colon
- ileitis may present with post-prandial pain, vomiting, RLQ mass; mimics acute appendicitis
- fistulae, fissures, abscesses are common
- extra-intestinal manifestations (see Table 11) are more common with colonic involvement
- linear ulcers leading to mucosal islands and “cobblestone” appearance
- deep fissures with risk of perforation into contiguous viscera (leads to fistulae and abscesses)
- enteric fistulae may communicate with skin, bladder, vagina and other parts of bowel
- granulomas are found in 50% of surgical specimens, 15% of mucosal biopsies

Investigations
- colonoscopy with biopsy to visualize (less often gastroscopy)
- CT/MR enterography to visualize small bowel
- CRP elevated in most new cases, useful to monitor treatment response
- bacterial cultures, O&P, C. difficile toxin to exclude other causes of inflammatory diarrhea

Figure 7. Traditional graded approach to induction therapy in Crohn’s disease

Note: Starting with immunosuppressives plus immunomodulators (“bottom-up approach”) increasingly being used (Lancet 2009;373:180-187). Combination of azathioprine and infliximab has the highest remission rate yet described with medical treatment (NEJM 2010;362:1383-1395).

Characteristically more than 1 yr between onset of symptoms and diagnosis of Crohn’s disease.
Management (also see Figure 7)

<td>Although the etiology of inflammatory bowel disease (IBD) is unknown, biological therapies (BT) that target key molecules in innate and adaptive immune pathways have been designed.</td>
</tr>
<tr>
<td></td>
<td>Anti-TNF Agents (infliximab, adalimumab, certolizumab): effective in CD, less effective for UC. Increase mucosal healing, decrease need for hospitalizations and surgeries, and can induce steroid-free remission. At least 10% of patients annually develop irremont due to BT and/or a loss of response.</td>
</tr>
<tr>
<td></td>
<td>Promising New BT: Anti-Interleukin-12/Interleukin-23 p40 target factors more often associated with CD, while anti–IFN-antibodies may treat CD and UC.</td>
</tr>
<tr>
<td></td>
<td>Selective Anti-Adhesion Molecules</td>
</tr>
<tr>
<td></td>
<td>BT Without Established Efficacy: Recombinant human cytokines, blockade of T-cell activation (daclizumab and basiliximab) and stimulators of the innate immune system.</td>
</tr>
<tr>
<td></td>
<td>Conclusion: Anti-TNF agents are effective treatments for IBD. There is a need to develop salvage biologic therapies for patients who do not respond to a first biological drug. BT’s have a safety risk, so their place in treatment algorithms must be defined carefully.</td>
</tr>
</tbody>
</table>

*Cholestyramine: a bile-salt binding resin; for watery diarrhea with <100 cm of terminal ileum diseased or resected; however, non-specific anti-diarrheals are more convenient and often more potent.

Prognosis

- highly variable course
- 10% disabled by the disease eventually, spontaneous remission also described
- increased mortality, especially with more proximal disease, greatest in the first 4-5 yr
- complications include:
  - intestinal obstruction/perforation
  - fistula formation
  - malignancy (lower risk compared to UC)
- surveillance colonoscopy same as ulcerative colitis (see below) if more than 1/3 of colon involved
Ulcerative Colitis (UC)

Definition
- inflammatory disease affecting colonic mucosa anywhere from rectum (always involved) to cecum

Epidemiology
- incidence 2-10/100,000; prevalence 35-100/100,000 (more common than Crohn’s)
- 2/3 onset by age 30 (with second peak after 50); M=F
- small hereditary contribution (15% of cases have 1st degree relative with disease)
- risk is less in smokers
- inflammation limited to rectum or left colon is more common than pancolitis

Pathology
- disease can involve any portion of lower bowel ranging from rectum only (proctitis) to entire colon (pancolitis)
- inflammation seen is diffuse, continuous and confined to mucosa

Clinical Features
- rectal bleeding is the hallmark feature, however diarrhea may be present if more than the rectum is involved
  - can also have abdominal cramps/pain, especially with defecation
  - severity of colonic inflammation correlates with symptoms (stool volume, amount of blood in stool)
  - tenesmus, urgency, incontinence
  - systemic symptoms: fever, anorexia, weight loss, fatigue in severe cases
  - extra-intestinal manifestations (see Table 11)
  - characteristic exacerbations and remissions; 5% of cases are fulminant

Investigations
- sigmoidoscopy with mucosal biopsy (to exclude self-limited colitis) without bowel prep often sufficient for diagnosis
- colonoscopy helpful to determine extent of disease; contraindicated in severe exacerbation
- CT colonography (formerly barium enema) if colonoscopy cannot be done; contraindicated in severe disease
- stool culture, microscopy, C. difficile toxin assay necessary to exclude infection
- no single confirmatory test

Management
- mainstays of treatment: 5-ASA (mesalamine) derivatives and corticosteroids, with azathioprine used in steroid-dependent or resistant cases
- diet of little value in decreasing inflammation but may alleviate symptoms
- antidiarrheal medications generally not indicated in UC
- 5-ASA
  - topical (suppository or enema): very effective for distal disease (distal to splenic flexure), preferable to corticosteroids
  - oral: effective for mild to moderate, but not severe colitis (4 g/d)
  - e.g. sulfasalazine 3-4 g/d, mesalamine 4 g/d
  - commonly used in maintaining remission (decreases yearly relapse rate from 60% to 15%)
  - may decrease rate of colorectal cancer
- corticosteroids
  - to remit acute disease, especially if severe or first attack; may need maximum dose IV steroids initially (e.g. methylprednisolone 30 mg IV q12h)
  - limited role as maintenance therapy
  - use suppositories for proctitis, enemas for proctosigmoiditis
  - topical steroids (e.g. hydrocortisone foam, budesonide enemas) for inflammation distal to splenic flexure
- immunosuppressants (steroid-sparing)
  - if severe UC is refractory to steroid therapy, consider adding IV cyclosporine or IV infliximab within 3-5 d of recognition of need for salvage – rapidly effective, but helpful only in a minority of patients
  - azathioprine: too slow to rapidly resolve acute relapse
    - most commonly used to induce and maintain remission as corticosteroids withdrawn
- surgical treatment
  - early in severe UC, especially fulminant cases and toxic megacolon – consider operation if no response after 3-5 d of corticosteroids, or after 4-7 d of immunosuppressive medical therapy
  - aim for cure with colectomy; bowel continuity can be restored with ileal pouch-anal anastomosis
  - indications: failure of adequate medical therapy, toxic megacolon, uncontrollable bleeding, pre-cancerous changes detected either by endoscopy or endoscopic biopsies (dysplasia), inability to taper corticosteroids

In UC, non-bloody diarrhea is frequently the initial presentation; eventually progressing to bloody diarrhea.
Figure 8. Medical management of severe ulcerative colitis

Complications
- similar to CD, except:
  - more liver problems (especially primary sclerosing cholangitis in men)
  - greater risk of colorectal cancer
    - risk increases with duration and extent of disease (5% at 10 yr, 15% at 20 yr for pancolitis; overall relative risk is 8%) 
    - risk also increases with active mucosal inflammation and sclerosing cholangitis 
    - thus, regular colonoscopy and biopsy in pancolitis of ≥8 yr is indicated
  - toxic megacolon (transverse colon diameter >6 cm on abdominal x-ray) with immediate danger of perforation (see General Surgery, GS26)

Prognosis
- chronic relapsing pattern in most patients 
- 10-15% chronic continuous pattern 
- >1 attack in almost all patients 
- more colonic involvement in the 1st year correlates with increased severity of attacks and increased colectomy rate 
  - colectomy rate = 1% for all patients after the 1st year; 20-25% eventually undergo colectomy 
  - normal life expectancy 
  - if proctitis only, usually benign course

Irritable Bowel Syndrome (IBS)

Definition
- a form of functional bowel disease, more than just a label for GI symptoms unexplained after investigations

Epidemiology
- 20% of North Americans 
- onset of symptoms usually in young adulthood 
- F>M
Pathophysiology

- associated with either abnormal perception of intestinal activity or abnormal intestinal motility
- abnormal motility: multiple abnormalities described; unclear if associations or if causative
- psychological: stress may increase IBS symptoms but does not cause IBS

Diagnosis

**Table 13. Rome III Criteria for Diagnosing Irritable Bowel Syndrome**

<table>
<thead>
<tr>
<th>IBS Rome III Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>≥12 wk in the past 12 mo of abdominal discomfort or pain that has 2 out of 3 features:</td>
</tr>
<tr>
<td>• Relieved with defecation</td>
</tr>
<tr>
<td>• Associated with a change in frequency of stool</td>
</tr>
<tr>
<td>• Associated with a change in consistency of stool</td>
</tr>
</tbody>
</table>

- The following are supportive, but not essential to the diagnosis:
  • Abnormal stool frequency (>3/d or <3/wk)
  • Abnormal stool form (lumpy/hard/loose/watery) >1/4 of defecations
  • Abnormal stool passage (straining, urgency, feeling of incomplete evacuation) >1/4 of defecations
  • Passage of mucus >1/4 of defecations
  • Bloating

**Diagnosis of IBS Less Likely in Presence of “Red Flag” Features**

- Weight loss
- Fever
- Nocturnal defecation
- Abnormal gross findings on flexible sigmoidoscopy

Normal Physical Exam

**Investigations**

- if history consistent with Rome III criteria, no alarm symptoms, and no family history of IBD or colorectal cancer, limited investigations required
- aim is to rule out diseases which mimic IBS
  • CBC, TSH, albumin, CRP, tTG serology with protein electrophoresis
  • stool for C&S, O&P, fat excretion if diarrhea present
  • consider sigmoidoscopy

**Management**

- reassurance, explanation, support, aim for realistic goals
- relaxation therapy, biofeedback, hypnosis, stress reduction
- no therapeutic agent consistently effective, pain most difficult to control
- symptom-guided treatment
  - pain predominant
    • antispasmodic medication before meals (e.g. hyoscine, pinaverium, trimebutine)
    • increase dietary fibre (bran or psyllium)
    • tricyclic antidepressants (TCA), selective serotonin reuptake inhibitors (SSRI)
  - diarrhoea predominant
    • increase dietary fibre (bran or psyllium) to increase stool consistency
    • loperamide (Imodium®)
    • diphenoxylate (Lomotil®)
    • cholestyramine 4 g QID
  - constipation predominant
    • exercise and increase fibre in diet
    • osmotic or other laxatives

**Prognosis**

- 80% improve over time
- most have intermittent episodes
- normal life expectancy

**Constipation**

**Definition**

- passage of infrequent or hard stools with straining (stool water <50 mL/d); bowel frequency <3 times/wk

**Epidemiology**

- increasing prevalence with age; F>M
- rare in Africa and India where stool weight is 3-4x greater than in Western countries
Etiology
• most common: idiopathic attributed to colon dysmotility but this is difficult to measure
• organic causes
  • medication side effects (narcotics, antidepressants) are the most common
  • intestinal obstruction, left sided colon cancer (consider in older patients) and fecal impaction
  • metabolic
    • diabetes mellitus
    • hyperthyroidism
    • hypercalcemia, hypokalemia, uremia
  • neurological
    • intestinal pseudo-obstruction
    • Parkinson's disease
    • multiple sclerosis
  • collagen vascular disease (e.g. scleroderma)
  • painful anal conditions (e.g. fissures)

Clinical Presentation
• overlaps with irritable bowel syndrome
• abdominal pain relieved by defecation, hard stools, straining and pain with defecation,
  flatulence, overflow diarrhea, tenesmus (sense of incomplete evacuation), abdominal distention,
  <3 BM/wk

Investigations
• consider colon visualization (colonoscopy, CT colonography), although chronic constipation by
  itself is rarely due to colonic mucosal disease
• classification based on colon transit time, can be quantitated by swallowing radio-opaque
  markers to measure colonic transit time (normal: 70 h)
  (1) normal = misperception of normal defecation (irritable bowel syndrome)
  (2) prolonged throughout = "colonic inertia" (infrequent bowel movements with gas/bloating,
    tends to occur in youth)
  (3) outlet obstruction = inability to coordinate pelvic floor muscles to empty rectum, straining,
    stool in rectum on digital exam, tends to occur in old age
• combination of (2) and (3) common

Treatment (in order of increasing potency)
• dietary fibre
  • useful if mild or moderate constipation, but not if severe
  • aim for 30 g daily, increase dose slowly
• surface-acting (soften and lubricate)
  • docusate salts, mineral oils
• osmotic agents (effective in 2-3 d)
  • lactulose, sorbitol, magnesium salts (e.g. magnesium hydroxide, aka milk of magnesia),
    lactitol, polyethylene glycol 3350
• cathartics/stimulants (effective in 24 h)
  • castor oil, senna (avoid prolonged use to prevent melanosis coli), bisacodyl
• enemas and suppositories (e.g. saline enema, phosphate enema, glycerin suppository, bisacodyl
  suppository)

Upper Gastrointestinal Bleeding

Definition
• bleeding proximal to the ligament of Treitz (75% of GI bleeds)
  • ligament of Treitz: suspensory ligament where fourth portion of the duodenum transitions to
    jejunum

Etiology
• above the GE junction
  • epistaxis
  • esophageal varices (10-30%)
  • esophagitis
  • esophageal cancer
  • Mallory-Weiss tear (10%)
• stomach
  • gastric ulcer (20%) (see Peptic Ulcer Disease, G12)
  • gastritis (e.g. from alcohol or post-surgery) (20%)
  • gastric cancer
  • gastric antral vascular ectasia (rare, associated with cirrhosis and CTD)
  • dieulofoy lesion (very rare)
• duodenum
  • ulcer in bulb (25%)
  • aortoenteric fistula: usually only if previous aortic graft (see sidebar)
• coagulopathy (drugs, renal disease, liver disease)
• vascular malformation (Dieulafoy’s lesion, AVM)

Clinical Features
• in order of decreasing severity of the bleed: hematochezia > hematemesis > coffee ground emesis > melena > occult blood in stool

Management (initial)
• stabilize patient (1-2 large bore IVs, IV fluids, monitor)
• send blood for CBC, cross and type, platelets, PT, PTT, electrolytes, BUN, Cr, LFTs
• keep NPO
• consider NG tube to determine upper vs. lower GI bleeding in some cases
• endoscopy (OGD): establish bleeding site + treat lesion
  • if bleeding peptic ulcer: most commonly used method of controlling bleeding is injection of epinephrine around bleeding point + thermal hemostasis (bipolar electrocoagulation or heater probe); less often thermal hemostasis may be used alone, but injection alone not recommended
  • endoclips
• IV PPI: decrease risk of rebleed if endoscopic predictors of rebleeding seen (see prognosis section)
  • given to stabilize clot, not to accelerate ulcer healing
  • if given before endoscopy, decreases need for endoscopic therapeutic intervention
• for variceal bleeds, octreotide 50 μg loading dose followed by constant infusion of 50 μg/h
• consider IV erythromycin (or metoclopramide) to accelerate gastric emptying prior to gastroscopy to remove clots from stomach

Prognosis
• 80% stop spontaneously
• peptic ulcer bleeding: low mortality (2%) unless rebleeding occurs (25% of patients, 10% mortality)
• endoscopic predictors of rebleeding: spurt or ooze, visible vessel, fibrin clot
• can send home if clinically stable, bleed is minor, no comorbidities, endoscopy shows clean ulcer with no predictors of rebleeding
• H₂–antagonists have little impact on rebleeding rates and need for surgery
• esophageal varices have a high rebleeding rate (55%) and mortality (29%)

Approach to Iron Deficiency Anemia

Overt GI bleeding (hematochezia, melena)

- Yes
  - Upper and lower endoscopy
  - Rule out non-GI sources of bleeding (e.g., hemorrhage, hemolysis)
  - Has the anemia resolved?
- No
  - Wireless endoscopy capsule/ double balloon endoscopy

* Wireless endoscopy capsule results help double balloon endoscopy localize source of bleeding
  • Angiography if overt bleeding hemodynamically significant, estimated >0.5 cc/min
  • CT enterography if wireless endoscopy capsule/double balloon endoscopy not available

Figure 9. Approach to iron deficiency anemia

Esophageal Varices

Etiology
• almost always due to portal hypertension
• often accompanied by varices in stomach

Clinical Features
• characteristically massive upper GI bleeding

Prognosis
• risk of bleeding: 30% in first year
• risk of rebleeding: 50-70% (20% mortality at 6 wk)

Transfusion Strategies for Acute Upper Gastrointestinal Bleeding

<table>
<thead>
<tr>
<th>Forrest Classification of Bleeding Peptic Ulcers</th>

<tr>
<td>l</td>
</tr>
</tbody>
</table>

Transfusion Strategies for Acute Upper Gastrointestinal Bleeding

- better survival, and fewer adverse events.
- Fewer patients in the restrictive group required transfusion (57% vs. 15%; P < 0.001). The hazard ratio for death for restrictive compared to liberal transfusion was 0.55; 95% CI, 0.33 to 0.92; P = 0.02. Further bleeding occurred in 10% vs. 16% (P = 0.01) of patients, while adverse effects occurred in 40% vs. 48% (P = 0.02) of patients in the restrictive and liberal strategies, respectively.
- The restrictive strategy had a better survival rate in patients with bleeding associated with cirrhosis Child-Pugh class A or B (HR: 0.30; 95% CI, 0.11 to 0.80), but not in cirrhosis Child-Pugh class C (HR: 1.04; 95% CI, 0.45 to 2.37) or a peptic ulcer (HR: 0.70; 95% CI, 0.26 to 1.95).
- Conclusions: Transfusing patients with an acute upper GI bleed at hemoglobin of <70 g/L rather than 90 g/L is associated with fewer transfusions, better survival, and fewer adverse events.

Review Article: Improved Survival with Patients with Variceal Bleeds

- Better survival, and fewer adverse events.
- Fewer patients in the restrictive group required transfusion (57% vs. 15%; P < 0.001). The hazard ratio for death for restrictive compared to liberal transfusion was 0.55; 95% CI, 0.33 to 0.92; P = 0.02. Further bleeding occurred in 10% vs. 16% (P = 0.01) of patients, while adverse effects occurred in 40% vs. 48% (P = 0.02) of patients in the restrictive and liberal strategies, respectively.
- The restrictive strategy had a better survival rate in patients with bleeding associated with cirrhosis Child-Pugh class A or B (HR: 0.30; 95% CI, 0.11 to 0.80), but not in cirrhosis Child-Pugh class C (HR: 1.04; 95% CI, 0.45 to 2.37) or a peptic ulcer (HR: 0.70; 95% CI, 0.26 to 1.95).
- Conclusions: Transfusing patients with an acute upper GI bleed at hemoglobin of <70 g/L rather than 90 g/L is associated with fewer transfusions, better survival, and fewer adverse events.

Esophageal varices are a common complication of portal hypertension, and their management includes medical, endoscopic, and surgical interventions. The Forrest classification provides a framework for understanding the severity of bleeding and guiding treatment decisions. The use of restrictive transfusion strategies has been shown to improve survival and reduce adverse events compared to liberal transfusion, especially in patients with cirrhosis. Always consider the underlying cause of variceal bleeding and tailor treatment accordingly. Always ask about NSAID/Aspirin or anticoagulant therapy in GI bleed.
Investigations
• endoscopy

Management

**Mallory-Weiss Tear**

**Definition**
• longitudinal laceration in gastric mucosa on lesser curvature near GE junction (20% straddle junction, 5% in distal esophagus)

**Etiology**
• due to rapid increases in gastric pressure from retching/vomiting against a closed glottis
• hiatus hernia usually present

**Clinical Features**
• hematemesis ± melena, classically following an episode of retching without blood
• can lead to fatal hematemesis

**Management**
• 90% stop spontaneously
• if persistent: endoscopy with epinephrine injection ± clips or surgical repair

**Lower Gastrointestinal Bleeding**

**Definition**
• bleed distal to ligament of Treitz

**Etiology**
• rule out upper GI source
• diverticular (60% from right colon)
• vascular
  • angiodysplasia
  • anorectal (hemorrhoids, fissures)
• neoplasm
• cancer
• polyps
• inflammation
  • colitis (ulcerative, infectious, radiation, ischemic)
• post-polypectomy

**Clinical Features**
• hematochezia (see Figure 11)
• anemia
• occult blood in stool
• rarely melena

**Management**
• treat underlying cause
**Figure 11. Approach to hematochezia**

### Liver

#### Investigations of Hepatobiliary Disease

**A. TEST OF LIVER FUNCTION**

**Prothrombin Time (PT or INR)**
- a marker of hepatic protein synthesis
- increased by:
  - impaired hepatic protein synthesis (>80%) (including all coagulation factors except VIII) i.e. hepatocellular dysfunction
  - vitamin K deficiency
  - vitamin K administration promptly corrects PT in vitamin K deficiency (malnutrition, malabsorption, etc.) but not in hepatocellular dysfunction; thus in the absence of vitamin K deficiency, PT is a reliable index of hepatocellular dysfunction

**Serum Albumin Level**
- a marker of hepatic protein synthesis; must exclude malnutrition, renal or GI losses and significant inflammatory or malignant illness of any organ system

**Serum Bilirubin**
- marker of hepatic excretion; transport from hepatocyte to bile
- canaliculus breakdown product of hemoglobin; metabolized in the reticuloendothelial system of liver, transported through biliary system, excreted via gut
- direct bilirubin = conjugated; indirect = unconjugated bilirubin
- liver dysfunction causes hyperbilirubinemia (elevated direct bilirubin) since conjugation preserved even in end stage liver failure

ALT > AST = most causes of hepatitis
AST > ALT = alcoholic liver disease or other causes of hepatitis that have progressed to advanced cirrhosis
B. TESTS OF LIVER DAMAGE
- disproportionately increased AST or ALT = hepatocellular damage
  - ALT more specific to liver; AST from multiple sources (especially muscle)
  - elevation of both highly suggestive of liver injury
  - most common cause of elevated ALT is fatty liver
- disproportionately increased ALP and GGT = cholestasis
  - if ALP is elevated alone, rule out bone disease by fractionating ALP
  - if ALP elevation out of proportion to ALT/AST elevation, consider:
    1. obstruction of common bile duct (extraluminal = pancreatic Ca, lymphoma; intraluminal = stones, cholangiocarcinoma, sclerosing cholangitis, helminths)
    2. destruction of microscopic ducts (e.g. PBC)
    3. bile acid transporter defects (drugs, intrahepatic cholestasis of pregnancy)
    4. infiltration of the liver (liver metastases, lymphoma, granulomas, amyloid)

Acute Viral Hepatitis (General)

Definition
- viral hepatitis lasting <6 mo

Clinical Features
- most are subclinical
- flu-like prodrome may precede jaundice by 1-2 wk
  - nausea, vomiting, anorexia, taste/smell disturbance, headaches, fatigue, myalgia, low-grade fever
  - arthralgia and urticaria (especially HBV)
- only some progress to icteric (clinical jaundice) phase, lasting days to weeks
  - pale stools and dark urine 1-5 d prior to icteric phase
  - hepatomegaly and RUQ pain
  - splenomegaly and cervical lymphadenopathy (10-20% of cases)

Investigations
- AST and ALT (>10-20x normal in hepatocellular necrosis)
- ALP and bilirubin minimally elevated
- viral serology, IgM

Treatment
- supportive (hydration, diet)
- indications for hospitalization: encephalopathy, coagulopathy severe vomiting, hypoglycemia

Prognosis
- poor prognostic indicators: comorbidities, persistently high bilirubin (>340 mmol; 20 mg/dL), increased INR, decreased albumin, hypoglycemia
- cholestasis (most commonly with HAV infection)

Complications
- hepatocellular necrosis: AST, ALT >10-20x normal, ALP and bilirubin minimally increased, increased cholestasis

Hepatitis A Virus (HAV)

- RNA virus
- fecal-oral transmission; incubation period 4-6 wk
- diagnosed by elevated transaminases, positive anti-HAV IgM
- in children: characteristically asymptomatic
- in adults: fatigue, nausea, arthralgia, fever, jaundice
- can cause fulminant hepatic failure and subsequent death (<1-5%)
- can relapse, but never becomes chronic

Hepatitis B Virus (HBV)

<table>
<thead>
<tr>
<th>Table 14. Hepatitis B Serology</th>
</tr>
</thead>
<tbody>
<tr>
<td>HBsAg</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>Acute HBV</td>
</tr>
<tr>
<td>Chronic HBV (high HBV DNA)</td>
</tr>
<tr>
<td>Chronic HBV (low HBV DNA)</td>
</tr>
<tr>
<td>Resolved infection</td>
</tr>
<tr>
<td>Immunization</td>
</tr>
</tbody>
</table>
Epidemiology
• 4 phases of chronic hepatitis B: not all will go through all 4 phases, but all will have positive HBsAg
  1. immune tolerance: extremely high HBV-DNA (>20,000 IU/mL), HBeAg positive, but normal ALT/AST; due to little immune control and minimal immune-mediated liver damage; characteristic of perinatal infection (or 'incubation period' in adult with newly-acquired HBV)
  2. immune clearance (or immunoactive): falling but still elevated HBV-DNA levels (>20,000 IU/mL), HBeAg positive; due to immune attack on the virus and immune-mediated liver damage; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment
  3. immune control: lower HBV-DNA (<20,000 IU/mL), HBeAg negative, anti-HBe positive, ALT/AST normal; due to immune control without immune-mediated liver damage; risk of reactivation to phase 2 (clinically resembles acute hepatitis B), especially with immunosuppression e.g. corticosteroids or chemotherapy
  4. immune escape (“core or precore mutant”): elevated HBV-DNA (>2,000 IU/mL), HBeAg negative because of pre-core or core promoter gene mutation, anti-HBe positive, ALT/AST high; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment

Management
• counselling: 40% of men and 10% of women with perinatal infection will die from HBV-related complications
• prolonged immune-mediated damage leads to higher risk of liver fibrosis
• hepatocellular carcinoma screening with ultrasound q6mo, especially if high serum HBV-DNA levels, cirrhosis, men, (age >40 in Asian men, >50 in Asian women, and >20 in African descent)
• consider pharmacological therapy if: 1. HBeAg positive + HBV-DNA >20,000 IU/mL + ALT >90; or 2. HBeAg negative + HBV-DNA >2,000 IU/mL + ALT >90 + stage ≥2 fibrosis on liver biopsy
• treat to prevent flare when placed on immunosuppressive therapy such as prednisone
• treatment goal: reduce serum HBV-DNA to undetectable level
• treatment options: interferon, tenofovir, entacavir, lamivudine, adefovir
• vaccinate against HAV if serology negative (to prevent further liver damage)
• follow blood and sexual precautions

Hepatitis D
• defective RNA virus requiring HBsAg for entry into hepatocyte, therefore infects only patients with hepatitis B; causes more aggressive disease than hepatitis B virus alone
• co-infection: acquire HDV and HBV at the same time
  ▪ better prognosis than superinfection (acute HDV infection on pre-existing HBV infection)
• HDV can present as fulminant hepatic failure (FHF) and/or accelerate progression to cirrhosis
• management: low-dose interferon (20% response) and liver transplant for end-stage disease

Hepatitis C Virus (HCV)
• RNA virus
• blood-borne transmission; sexual transmission is "inefficient"
• major risk factor: injection drug use
• other risk factors: blood transfusion received before 1992 (or received in developing world), tattoos, intranasal cocaine use
• clinical manifestation develops 6-8 wk after exposure
  ▪ symptoms mild and vague (fatigue, malaise, nausea) therefore not commonly diagnosed in acute stage

Risk of hepatocellular carcinoma in HBV increases with increasing age, which is likely a surrogate for increasing liver fibrosis/cirrhosis.

Risk of hepatocellular carcinoma in HCV increases only after cirrhosis develops.

Without treatment, 8-20% of those with ongoing immunoactive chronic hepatitis can develop cirrhosis within 5 yr. In contrast, those in the immune tolerant phase (with extremely high HBV-DNA levels) are at minimal risk for liver fibrosis as they do not have immune-mediated liver injury.

In acute hepatitis B, HDV co-infection increases severity of hepatitis but does not increase risk of progression to chronic hepatitis. However in the context of chronic hepatitis B, superinfection with HDV increases progression to cirrhosis.
Diagnosis
- suspected on basis of elevated ALT/AST and positive serum anti-HCV
- diagnosis established by detectable HCV-RNA in serum
- virus genotype correlates with response to treatment but not prognosis
- serum HCV-RNA inversely correlates with response to treatment
- normal transaminases can have underlying cirrhosis on biopsy, but otherwise excellent prognosis

Management
- blood-borne precautions; vaccinate for hepatitis B and A if serology negative, avoid alcohol
- clearest indication for treatment is in subgroup likely to develop clinically significant liver disease
- persistently elevated transaminases, liver biopsy shows fibrosis/cirrhosis and at least moderately severe necrosis/inflammation
- indicators of poor response to treatment: cirrhosis, genotype 1, high HCV-RNA, co-infection with HIV, African-American race
- pegylated interferon-α + ribavirin aims to clear HCV infection, but only 50-80% success rate and side effects common (therefore not all patients are treated)
  - general adverse effects: depression/fatigue, hemolysis, bone marrow suppression (monitor CBC regularly), fevers/myalgia, precipitates autoimmune diseases (rare), skin rashes
  - recently introduced protease inhibitors for genotype I (most common, least amenable to treatment) have significantly increased sustained remission rate to up to 70%

Prognosis
- 80% of acute hepatitis C become chronic (of these 20% evolve to cirrhosis)
- risk of hepatocellular carcinoma increases if cirrhotic
- can cause cryoglobulinemia; associated with membranoproliferative glomerulonephritis, lymphoma

</table>

Autoimmune Chronic Active Hepatitis

- Diagnosis of exclusion: rule out viruses, drugs, metabolic or genetic causes
- Can be severe: 40% mortality at 6 mo without treatment
- Extrahepatic manifestations
  - sicca, Raynaud’s, thyroiditis, Sjögren’s, arthralgias
  - Hypergammaglobulinemia
    - Anti-smooth muscle antibody elevation is most characteristic; also elevations in anti-LKM (liver, kidney microsome, especially in children)
    - Less specific: elevated ANA, RF
    - Can have false positive viral serology (especially anti-HCV)
    - Biopsy – periportal (zone 1) and “interface” inflammation and necrosis
- Management: corticosteroids (80% respond) ± azathioprine (without this, most will relapse as corticosteroids are withdrawn)

Specific Drugs

- Acetaminophen
  - Metabolized by hepatic cytochrome P450 system
  - Can cause FHF (transaminases >1,000 U/L followed by jaundice and encephalopathy)
  - Requires 10-15 g in healthy, 4-6 g in alcoholics/anticonvulsant users
  - Mechanism: high acetaminophen dose saturates glucuronidation and sulfation elimination pathways → reactive metabolite is formed → covalently binds to hepatocyte membrane
  - Presentation:
    - First 24 h: nausea and vomiting (usually within 4-12 h of overdose)
    - 24-48 h: asymptomatic, but ongoing hepatic necrosis resulting in increased transaminases
    - >48 h: continued hepatic necrosis possibly complicated with FHF or resolution
  - Note: potential delay in presentation in sustained-release products
  - Blood levels of acetaminophen correlate with the severity of hepatic injury, particularly if time of ingestion known
  - Therapy:
    - Gastric lavage/emesis (if <2 h after ingestion)
    - Oral activated charcoal
    - N-acetylcysteine (NAC, Mucomyst*) can be given PO or IV (most effective within 8-10 h of ingestion, but should be given no matter when time of ingestion)
      - Promotes hepatic glutathione regeneration
    - No recorded fatal outcomes if NAC given before increase in transaminases
    - Chlorpromazine: cholestasis in 1% after 4 wk; often with fever, rash, jaundice, pruritus and eosinophilia
• INH (isoniazid)
  ▪ 20% develop elevated transaminases but <1% develop clinically significant disease
  ▪ susceptibility to injury increases with age
• methotrexate
  ▪ causes cirrhosis; increased risk in the presence of obesity, diabetes, alcoholism (i.e. with
    underlying risk for pre-existing fatty liver)
  ▪ scarring develops without symptoms or changes in liver enzymes, therefore biopsy may be
    needed in long-term treatment
• amiodarone: can cause same histology and clinical outcome as alcoholic hepatitis
• others: azoles, statins, methyldopa, phenytoin, propylthiouracil (PTU), rifampin, sulfonamides,
  tetracyclines
• herbs: chaparral, Chinese herbs (e.g. germander, comfrey, bush tea)

Wilson’s Disease

Definition
• autosomal recessive defect in copper metabolism (gene ATP7B)

Pathology
• decreased biliary excretion of copper plus decreased incorporation of copper into ceruloplasmin

Clinical Manifestations
• liver: acute hepatitis, fulminant liver failure, chronic active hepatitis, cirrhosis, low risk of
  hepatocellular carcinoma
• eyes: Kayser-Fleischer rings (copper deposits in Descemet’s membrane); more common in
  patients with CNS involvement, present in 50% if only liver involvement
• CNS: basal ganglia (wing flapping tremor, Parkinsonism), cerebellum (dysarthria, dysphagia,
  incoordination, ataxia), cerebrum (psychosis, affective disorder)
• kidneys: Fanconi’s syndrome (proximal tubule transport defects) and stones
• blood: intravascular hemolysis; may be initial presentation in fulminant hepatitis
• joints: arthritis, bone demineralization, calcifications

Investigations
• suspect if increased liver enzymes with clinical manifestations at young age (<30); especially
  combination of liver disease with dystonia, psychiatric symptoms
• screening tests:
  1. reduced serum ceruloplasmin (<50% of normal)
  2. Kayser-Fleischer rings (usually require slit-lamp examination)
  3. increased urinary copper excretion
• gold standard:
  1. increased copper on liver biopsy by quantitative assay
  2. genetic analysis imperfect as many mutations in ATP7B are possible

Treatment
• 4 drugs available:
  1. penicillamine chelates copper, poorly tolerated
  2. trientine chelates copper
  3. zinc impairs copper excretion in stool/ decreases copper absorption from gut
  4. tetrathiomolybdate preferred if neurological involvement
• screen relatives
• liver transplant in severe cases

Hemochromatosis

Definition
• excessive iron storage causing multiorgan system dysfunction (liver, in particular) with total
  body stores of iron increased to 20-40 g (normal 1 g)

Etiology
• primary hemochromatosis
  ▪ primarily due to common recessive gene (HFE, 5%); 1/400 patients are homozygotes
  ▪ results in ongoing gut absorption of iron despite adequate iron stores
• secondary hemochromatosis
  ▪ parenteral iron overload (e.g. transfusions)
  ▪ chronic hemolytic anemia: thalassemia, pyruvate kinase deficiency
  ▪ excessive iron intake

Gene mutation not 100% penetrant: so not all with homozygous gene defect have clinically significant iron overload.
Clinical Features
- usually presents with trivial elevation in serum transaminases
- liver: cirrhosis (30%), HCC (200x increased risk) – most common cause of death (1/3 of patients)
- pancreas: diabetes, chronic pancreatitis
- skin: bronze or grey (due to melanin, not iron)
- heart: dilated cardiomyopathy
- pituitary: hypogonadotropic hypogonadism (impotence, decreased libido, amenorrhea)
- joints: arthralgia (any joint, but especially MCP joints), chondrocalcinosis

Investigations
- screening for individuals with clinical features and/or family history (1/4 chance of sibling having the disease)
  - transferrin saturation (free Fe²⁺/TIBC) >50%
  - serum ferritin >400 ng/mL
  - HFE gene analysis: 90% of primary hemochromatosis involves C282Y allele, while H63D and S65C alleles also commonly involved and screened
- liver biopsy (to define degree of iron overload and to detect cirrhosis)
  - usually indicated if age >40, ALT/AST more than 2.5 times the upper limit of normal, or ferritin >1000
- HCC screening if cirrhosis

Treatment
- phlebotomy: weekly or q2wk then lifelong maintenance phlebotomies q2-6mo
- deferoxamine if phlebotomy contraindicated (e.g. cardiomyopathy, anemia)
- primary hemochromatosis responds well to phlebotomy
- secondary hemochromatosis usually requires chelation therapy (administration of agents that bind and sequester iron, and then excreted)

Prognosis
- normal life expectancy if treated before the development of cirrhosis or diabetes

Alcoholic Liver Disease

Types of Lesions
- fatty liver (all alcoholics): always reversible if alcohol stopped
- alcoholic hepatitis (35% of alcoholics): usually reversible if alcohol stopped
- cirrhosis (10-15% of alcoholics): potentially irreversible

Pathophysiology
- several mechanisms, poorly understood
- ethanol oxidation to acetaldehyde:
  - reduces NAD⁺ to NADH; increased NADH decreases ATP supply to liver, impairing lipolysis so fatty acids and triglycerides accumulate in liver
  - binds to hepatocytes evoking an immune reaction
- ethanol increases gut permeability leading to increased bacterial translocation
- alcohol metabolism causes:
  - relative hypoxia in liver zone III > zone I
  - necrosis and hepatic vein sclerosis
- histology of alcoholic hepatitis:
  - ballooned (swollen) hepatocytes often containing Mallory bodies, characteristically surrounded by neutrophils
  - large fat globules
  - fibrosis: space of Disse and perivenular

Clinical Features
- >2-3 standard drinks/d in females and >3-6 standard drinks/d in men for >10 yr leads to cirrhosis, but only in about 10 to 20% of those who consume this amount daily on a continuous basis; cirrhosis risk increases with amount of alcohol consumed above threshold
- clinical findings do not accurately predict type of liver involvement
  - fatty liver:
    - mildly tender hepatomegaly; jaundice rare
    - mildly increased transaminases <5x normal
  - alcoholic hepatitis:
    - variable severity: mild to fatal liver failure
    - mild: stops drinking because feels unwell, resumes when feeling better (if assessed, findings of hepatitis, potentially mild jaundice and mildly elevated INR)
    - severe: stops drinking but feels unwell, low grade fever, RUQ discomfort, increased white blood cell count – mimics RLL pneumonia and cholecystitis

Standard Drink Equivalent
- 1 standard drink= 14 g EtOH
  = 12 oz beer (5% alcohol)
  = 5 oz wine (12-17%)
  = 3 oz fortified wine (17-22%)
  = 1.5 oz liquor (40%)
Tip: Percentage alcohol multiplied by oz roughly equals 60
- Blood tests are non-specific, but in general:
  - AST/ALT > 2:1 (usually < 300)
  - Increased GGT
  - CBC: Increased MCV (mean corpuscular volume), increased WBC
- Prognosis: Maddrey's discriminant function (based on PT and bilirubin) predicts mortality

### Treatment
- Alcohol cessation (see Psychiatry, PS22)
  - Alcoholics Anonymous, disulfiram, naltrexone, acamprosate
- Multivitamin supplements (especially thiamine)
- Caution with drugs metabolized by the liver
- Prednisone 40 mg OD x 28 d (taper over 2-4 wk) in subgroup with elevated bilirubin and INR, or if encephalopathy; but contraindicated in GI bleeding, renal failure, infection
- Pentoxyphilline decreases TNF, shown in one trial to reduce death, albeit only from renal failure, favourable side-effect profile

### Prognosis
- Fatty liver: complete resolution with cessation of alcohol intake
- Alcoholic hepatitis mortality
  - Immediate: 30%-60% in the first 6 mo if severe
  - With continued alcohol: 70% in 5 yr
  - With cessation: 30% in 5 yr

### Non-Alcoholic Fatty Liver Disease (NAFLD)

#### Etiology/Epidemiology
- Spectrum of disorders characterized by macrovesicular hepatic steatosis
- Most common cause of liver disease in North America

#### Pathophysiology
- Pathogenesis not well elucidated; insulin resistance implicated as key mechanism, leading to hepatic steatosis
- Changes indistinguishable from those of alcoholic hepatitis despite negligible history of alcohol consumption

#### Risk Factors
- Likely a component of the metabolic syndrome along with type II diabetes, hypertension, hypertriglyceridemia
- Rapid weight loss or weight gain

#### Clinical Features/Investigations
- Often asymptomatic
- May present with fatigue, malaise and vague RUQ discomfort
- Elevated serum triglyceride/cholesterol levels and insulin resistance
- Elevated serum AST, ALT ± ALP; AST/ALT < 1
- Presents as echogenic liver texture on ultrasound
- Liver biopsy diagnostic, but often necessary only for prognosis

#### Management
- No proven effective therapy other than gradual weight loss
- Some evidence for vitamin E (800 U daily); pioglitazone if diabetes concomitantly present
- Modification of risk factors is generally recommended, especially gradual weight reduction
- Optimization of therapy for diabetes, hyperlipidemia, hypertension

#### Prognosis
- Most die from cardiovascular or cerebrovascular disease
- Better prognosis than alcoholic hepatitis
  - < 25% progress to cirrhosis over a 7-10 yr period
- Risk of progression increases if inflammation or scarring occurs alongside fat infiltration (non-alcoholic steatohepatitis)
- Other clinical indicators of unfavourable prognosis: diabetes, age, metabolic syndrome
Acute Liver Failure (ALF; Formerly Fulminant Hepatic Failure)

Definition
- severe decline in liver function characterized by coagulation abnormality (INR>1.5) and encephalopathy
- in setting of previously normal liver
- rapid (<26 wk duration)

Etiology
- drugs (especially acetaminophen), hepatitis B (measure IgM anti-HBc because sometimes HBV-DNA and even HBsAg rapidly becomes negative), hepatitis A, hepatitis C (rare), ischemic, idiopathic

Management
- correct hypoglycemia, monitor level of consciousness, prevent GI bleeding with PPI, vigilant for infection and multiorgan failure (usually requires ICU)
- consider liver biopsy before INR becomes too high
- chief value is to exclude chronic disease, less helpful for prognosis
- liver transplant: consider early, especially if time from jaundice to encephalopathy >7 d (e.g. not extremely rapid), age <10 or >40, cause is drug or unknown, bilirubin >300 µmol/L, INR >3.5, creatinine >200 µmol/L

Cirrhosis

Definition
- liver damage characterized by diffuse distortion of the basic architecture and replacement with scar tissue and formation of regenerative nodules
- Stage 1 cirrhosis is compensated and asymptomatic, can last for 10-20 yr with almost normal life expectancy
- Stage 2 cirrhosis is the onset of first decompensation, typically development of ascites (most common), varical bleeding, encephalopathy

Etiology
- fatty liver (alcohol, metabolic syndrome)
- chronic viral hepatitis (B, B+D, C; not A or E)
- autoimmune hepatitis
- hemochromatosis
- α1-antitrypsin deficiency
- primary biliary cirrhosis
- chronic hepatic congestion
  - cardiac cirrhosis (chronic right heart failure, constrictive pericarditis)
  - hepatic vein thrombosis (Budd-Chiari)
- idiopathic
- rare: Wilson's disease, Gaucher's disease

Diagnosis
- definitive diagnosis is histologic (liver biopsy)
- other tests may be suggestive:
  - blood work: fall in platelet count <150 is the earliest finding, followed many yr later with rise in INR, fall in albumin, rise in bilirubin, fall in glucose level (pre-terminal event; see Figure 13)
  - FibroTest: combination of various clinical and biochemical markers that can predict degree of fibrosis
  - imaging:
    - U/S is the primary imaging modality but only finds advanced cirrhosis
    - CT to look for varices, nodular liver texture, splenomegaly, ascites
    - FibroScan: non-invasive tool using elastography (variable availability)
    - gastroscopy: varices or portal gastropathy

Management
- treat underlying disorder
- decrease insults (e.g. alcohol cessation, hepatotoxic drugs)
- follow patient for complications (esophageal varices, ascites, HCC defines stage 2 cirrhosis)
- prognosis: Child-Pugh Score (see Table 17)
- liver transplantation for end-stage disease if no alcohol for >6 mo; use MELD stratification (see sidebar)

**MELD (Model for End Stage Liver Disease)**
- Predicts 3-mo survival and used to stratify patients on transplant list
- Based on creatinine, INR and total bilirubin
Table 17. Child-Pugh Score and Interpretation

Score: 5-6 (Child’s A), 7-9 (Child’s B), 10-15 (Child’s C)

*Note: Child’s classification is rarely used for shunting, but is still useful to quantitate the severity of cirrhosis

**Complications**

- hematologic changes in cirrhosis
  - pancytopenia from hypersplenism: platelets first, then WBC, then hemoglobin
  - decreased clotting factors resulting in elevated INR, thus tendency for bruising and bleeding
- variceal bleeds
  - half of patients with cirrhosis have gastroesophageal varices and one-third of these develop hemorrhage with an overall mortality of >30%
  - hepatic venous pressure gradient (HVPG) ≥10 mmHg is the strongest predictor of variceal development
  - management: resuscitation, antibiotic prophylaxis, vasoactive drugs combined with endoscopic band ligation or sclerotherapy, TIPS
- renal failure in cirrhosis
  - classifications
    - pre-renal (usually due to over-diuresis)
    - acute tubular necrosis (ATN)
    - hepatorenal syndrome (HRS)
      - Type I: sudden and acute renal failure (rapid doubling of creatinine over 2 wk)
      - Type II: gradual increase in creatinine with worsening liver function (creatinine doubling over years)
    - HRS can occur at any time in severe liver disease, especially after:
      - overdiuresis or dehydration, such as diarrhea, vomiting, etc.
      - GI bleed
      - sepsis
    - treatment for hepatorenal syndrome (generally unsuccessful at improving long term survival)
      - for type I HRS: octreotide + midodrine + albumin (increases renal blood flow by increasing systemic vascular resistance)
      - definitive treatment is liver transplant
- hepatopulmonary syndrome
  - majority of cases due to cirrhosis, though can be due to other chronic liver diseases, such as non-cirrhotic portal hypertension
  - thought to arise from ventilation-perfusion mismatch, intrapulmonary shunting and limitation of oxygen diffusion, failure of damaged liver to clear circulating pulmonary vasodilators vs. production of a vasodilating substance by the liver
  - clinical features:
    - hyperdynamic circulation with cardiac output >7 L/min at rest and decreased pulmonary + systemic resistance (intrapulmonary shunting)
    - dyspnea, platypnea (increase in dyspnea in upright position, improved by recumbency) and orthodeoxia (desaturation in the upright position, improved by recumbency)
    - diagnosis via contrast-enhanced echocardiography: inject air bubbles into peripheral vein; air bubbles appear in left ventricle after third heartbeat (normal = no air bubbles; in ventricular septal defect, air bubbles seen <3 heart beats)
    - only proven treatment is liver transplantation

**Hepatorenal Syndrome vs. Pre-renal Failure – difficult to differentiate:**

- Similar blood and urine findings, (see Nephrology, NP33)
- Urine sodium: very low in hepatorenal; low in pre-renal
- Intravenous fluid challenge: giving volume expanders improves pre-renal failure, but not hepatorenal syndrome
Hepatocellular Carcinoma (HCC)

- see General Surgery, GS43

Liver Transplantation

- see General Surgery, GS44

Portal Hypertension

Definition
- pressure gradient between hepatic vein pressure and wedged hepatic vein pressure (corrected sinusoidal pressure) >5 mmHg

Pathophysiology
- 3 sites of increased resistance (remember pressure = flow x resistance)
  - pre-sinusoidal (e.g. portal vein thrombosis, schistosomiasis, sarcoidosis)
  - sinusoidal (e.g. cirrhosis, alcoholic hepatitis)
  - post-sinusoidal (e.g. right-sided heart failure, hepatic vein thrombosis, veno-occlusive disease, constrictive pericarditis)

Complications
- GI bleeding from varices in esophagus, less commonly in stomach, even less frequently from portal hypertensive gastropathy
- ascites
- hepatic encephalopathy
- thrombocytopenia
- renal dysfunction
- sepsis
- arterial hypoxemia

Management
- non-selective β-blockers (propanolol, nadolol) decrease risk of bleeding from varices
- transjugular intrahepatic portosystemic shunt (TIPS): to decrease portal venous pressure
  - shunt between portal and hepatic vein via transjugular vein catheterization and percutaneous puncture of portal vein
  - can be used to stop acute bleeding or prevent rebleeding or treat ascites
  - shunt usually remains open for <1 yr
  - complications: hepatic encephalopathy, deterioration of hepatic function
  - contraindicated with severe liver dysfunction
  - most commonly used as a “bridge” to liver transplant
- other surgically created shunts (rare): portacaval, distal spleno-renal (Warren shunt)

Hepatic Encephalopathy

Definition
- spectrum of potentially reversible neuropsychiatric syndromes secondary to liver disease diagnosed after ruling out other causes for symptoms (e.g. structural/metabolic)

Pathophysiology
- portosystemic shunt around hepatocytes and decreased hepatocellular function increase level of systemic toxins (believed to be ammonia from gut, mercaptans, fatty acids, amino acids) which go to the brain
Precipitating Factors
- nitrogen load (GI bleed, protein load from food intake, renal failure, constipation)
- drugs (narcotics, CNS depressants)
- electrolyte disturbance (hypokalemia, alkalosis, hypoxia, hypovolemia)
- infection (spontaneous bacterial peritonitis)
- deterioration in hepatic function or superimposed liver disease

Stages
- I: apathy, restlessness, reversal of sleep-wake cycle, slowed intellect, impaired computational abilities, impaired handwriting
- II: asterixis, lethargy, drowsiness, disorientation
- III: stupor (rousable), hyperactive reflexes, extensor plantar responses
- IV: coma (response to painful stimuli only)

Investigations
- clinical diagnosis: supported by laboratory findings and exclusion of other neuropsychiatric diseases
- rule out:
  - non-liver-related neuropsychiatric disease in a patient with liver problems (e.g. alcohol withdrawal or intoxication, sedatives, subdural hematoma, metabolic encephalopathy)
  - causes of metabolic encephalopathy (e.g. renal failure, respiratory failure, severe hyponatremia, hypoglycemia)
- characteristic EEG findings: diffuse (non-focal), slow, high amplitude waves

Treatment
- treat underlying precipitating factors
- decrease generation of nitrogenous compounds
  - decrease dietary protein to 50 g/d; vegetable protein is better tolerated than animal protein
  - lactulose: titrated to achieve 2 to 3 soft stools per day
    - prevents diffusion of NH₃ (ammonia) from the colon into blood by lowering pH and forming non-diffusible NH₄ (ammonium)
    - serves as a substrate for incorporation of ammonia by bacteria, promotes growth in bowel lumen of bacteria which produce minimal ammonia
    - also acts as a laxative to eliminate nitrogen-producing bacteria from colon
  - if inadequate response with lactulose may try antibiotics
    - broad-spectrum antibiotics (metronidazole, rifaximin) eliminate ammonia producing bacteria from bowel lumen
    - non-absorbable antibiotic rifaximin probably most effective treatment but only available through special access in Canada
- best acute treatment in comatose patient is tap water or lactulose enemas

Ascites

Definition
- accumulation of excess fluid in the peritoneal cavity

Etiology

Table 18. Serum-Ascites Albumin Gradient as an Indicator of the Causes of Ascites

<table>

* In nephrotic syndrome: decreased serum [Alb] to begin with therefore gradient not helpful

Pathogenesis
- key factor in pathogenesis is increased sodium (and water) retention by the kidney for reasons not fully understood. Theories include:
  - underfill hypothesis: first step in ascites formation is increased portal pressure and low oncotic pressure (e.g. low serum albumin) driving water out of the splanchnic portal circulation into abdominal cavity; the resulting decreased circulating volume causes secondary sodium retention by the kidney
  - overfill hypothesis: cirrhosis directly causes increased sodium retention by the kidney in the absence of hypovolemia and ascites arises secondarily
  - peripheral arterial vasodilation theory (most popular): as portal hypertension develops in cirrhosis, production of local mediators such as nitric oxide lead to splanchnic arterial vasodilation which ultimately results in reduction of effective arterial volume and compensatory sodium and fluid retention by the kidneys (i.e. circulation volume is increased, as per overflow hypothesis, but relatively underfilled, as per underfill hypothesis)
Diagnosis
- abdominal ultrasound
- physical exam (clinically detectable when >500 mL):
  - bulging flanks, shifting dullness, fluid-wave test positive
  - most sensitive symptom: ankle swelling

Investigations
- diagnostic paracentesis
  - 1st aliquot: cells and differential
  - 2nd aliquot: chemistry (especially albumin, but also total protein; amylase if pancreatitis, TG if turbid and suspect chylous ascites)
  - 3rd aliquot: C&S, Gram stain
  - 4th aliquot: cytology (usually positive in peritoneal carcinomatosis)

Treatment
- non-refractory ascites:
  - Na+ restriction (daily sodium intake <2 g)
  - diuretics: spironolactone, furosemide
  - aim for weight loss 0.5-1 kg/d, more if concomitant peripheral edema (which is mobilized quicker than ascitic fluid); overly rapid weight loss increases risk of renal failure
  - double diuretic dose every 2-4 wk to achieve weight loss target
- refractory ascites (treatment with diuretics are inadequate or not tolerated):
  - therapeutic/palliative paracentesis indicated
  - IV albumin (not indicated if <5 L removed by paracentesis)
  - TIPS usually provides temporary benefit in controlling ascites but no survival advantage
  - liver transplantation should be considered in every case, since development of ascites in patients with cirrhosis are associated with 50% 2-yr mortality

Complication: Primary/Spontaneous Bacterial Peritonitis (SBP)
- primary/spontaneous bacterial peritonitis (SBP)
- complicates ascites, but does not cause it (occurs in 10% of cirrhotic ascites); higher risk in patients with GI bleed
- 1/3 of patients are asymptomatic, thus do not hesitate to do a diagnostic paracentesis in ascites even if no clinical indication of infection
- fever, chills, abdominal pain, ileus, hypotension, worsening encephalopathy, acute kidney injury
- Gram-negatives compose 70% of pathogens: E. coli (most common), Streptococcus, Klebsiella

• diagnosis
  - absolute neutrophil count in peritoneal fluid >0.25x10⁹ cells/L (250 cells/mm³)
  - Gram stain positive in only 10-50% of patients
  - culture positive in <80% of patients (not needed for diagnosis)

• prophylaxis: consider in patients with
  - cirrhosis or GI bleed: IV ceftriaxone daily or norfloxacin bid x 7 d
  - previous episode of SBP, long-term prophylaxis with daily norfloxacin or TMP-SMX

• treatment
  - IV antibiotics (cefotaxime 2 g IV q8h is the treatment of choice for 5 d; modify if response inadequate or culture shows resistant organisms)
  - IV albumin (1.5 g/kg at time of diagnosis and 1 g/kg on day 3) decreases mortality by lowering risk of acute renal failure

Primary Prophylaxis of Spontaneous Bacterial Peritonitis Delays Hepatorenal Syndrome and Improves Survival in Cirrhosis
Gastroenterology 2007;133:818-824

Study: RCT, double-blinded study with 1 yr follow-up.
Population: 68 patients with cirrhosis, ascites, ascitic fluid protein <15 g/L and impaired renal function or severe liver failure.
Intervention: General, regional or combined anesthesia to patients undergoing a surgical procedure.
Main Outcome: Norfloxacin versus placebo.
Results: There was a significant reduction of patients developing spontaneous bacterial peritonitis (SBP) (6% vs. 30%, p=0.02) and spontaneous bacteremia (6% vs. 12%, p=0.05) with norfloxacin therapy. There were significantly fewer patients who developed all-cause renal failure (7 vs. 16, p=0.03) and hepatorenal syndrome (HRS) with norfloxacin therapy. Probability of survival at 3 mo (94% vs. 62%, p=0.02) and 1 yr (60% vs. 48%, p=0.003) were high in patients treated with norfloxacin.
Conclusion: Primary prophylaxis with norfloxacin in patients with advanced cirrhosis reduced SBP, HRS, and improved 1 yr survival.

Biliary Tract

Jaundice
- see Table 2, Figures 15 and 16

Signs and Symptoms
- dark urine, pale stools: suggests that bilirubin elevation is from direct fraction
- pruritus: suggests chronic disease, cholestasis
- abdominal pain: suggests biliary tract obstruction from stone or pancreatic tumour (obstructive jaundice)
- painless jaundice in the elderly: think of pancreatic cancer, although most patients with pancreatic cancer have pain
- kerneicterus: rarely seen in adults due to maturation of blood brain barrier
Investigations
- blood work: CBC, bilirubin (direct and total), liver enzymes (AST, ALT, ALP, GGT), liver function tests (INR/PT, PTT, albumin), amylase
- U/S or CT for evidence of bile duct obstruction (e.g. bile duct dilation)
- direct bile duct visualization
  - magnetic resonance cholangiopancreatography (MRCP): non-invasive
  - endoscopic ultrasound (EUS): sensitive for stones and pancreatic tumours
  - endoscopic retrograde cholangiopancreatography (ERCP): invasive, most accurate, allows for therapeutic intervention
  - percutaneous transhepatic cholangiography (PTC): if ERCP fails, if obstruction is in liver

Figure 16. Approach to jaundice

Gilbert’s Syndrome

Definition
- mild decrease in glucuronyltransferase activity leading to defective conjugation of bilirubin

Etiology/Epidemiology
- some patients have decreased hepatobiliary uptake
- affects 7% of population, especially males
- autosomal dominant, 70% due to a mutation in the UGT gene

Signs and Symptoms
- presents in teens-20s, often an incidental finding
- only manifestation is intermittent jaundice with increased serum unconjugated bilirubin developing most characteristically while fasting; no other clinical implications

Treatment
- none indicated (entirely benign)

Sclerosing Cholangitis

Definition
- inflammation of biliary tree (intra and/or extrahepatic bile ducts) leading to scarring and lumen obliteration

Etiology
- primary/idiopathic (most common)
  - associated with IBD, more commonly UC, in up to 70% of patients (usually male)
  - one of the most common indications for transplant
- secondary (less common)
  - long-term choledocholithiasis
  - cholangiocarcinoma
  - surgical/traumatic injury (iatrogenic)
  - contiguous inflammatory process
  - post-ERCP
  - associated with HIV/AIDS (“HIV cholangiopathy”)
Signs and Symptoms
- often insidious, may present with fatigue and pruritus
- may present with signs of episodic bacterial cholangitis secondary to biliary obstruction

Diagnosis
- increased ALP (hallmark), less often increased bilirubin
- mildly increased AST, usually <300 U/L
- p-ANCA (30-80%), elevated IgM (40-50%)
- ERCP shows narrowing and dilatations of bile ducts that may result in “beading”, both intrahepatic and extrahepatic bile ducts
  - if intrahepatic narrowing only, do anti-mitochondrial antibody to rule out PBC

Complications
- repeated bouts of cholangitis may lead to complete biliary obstruction with resultant secondary biliary cirrhosis and hepatic failure
- increased incidence of cholangiocarcinoma (10-15%): difficult to diagnose and treat

Management
- image bile duct (MRCP) at least annually for early detection of cholangiocarcinoma
- endoscopic sphincterotomy, biliary stent in selected cases of dominant CBD stricture
- antibiotics for cholangitis
- suppurative cholangitis requires emergency drainage of pus in CBD
- liver transplantation appears the best treatment for advanced sclerosing cholangitis (nearly 90% 1-yr survival; mean follow-up from time of diagnosis to need for transplant is 10 yr)
- ursodiol: previously recommended, but studies suggest that at least in high doses it increases mortality

Prognosis
- unfavourable regardless of treatment
- mean survival after diagnosis remains 4-10 yr

Primary Biliary Cirrhosis (PBC)

Definition
- chronic inflammation and fibrous obliteration of intrahepatic bile ductules

Etiology/Epidemiology
- likely autoimmune (associated with Sjögren’s syndrome, scleroderma, CREST syndrome, RA, thyroiditis)
- affects mainly middle-aged women (M:F = 1:9)

Signs and Symptoms
- often asymptomatic
- initial symptoms: pruritus, fatigue
- chronic: jaundice and melanosis (darkening skin) and other signs of cholestasis
- end-stage: hepatocellular failure, portal hypertension, ascites
- high incidence of osteoporosis

Investigations
- increased ALP, GGT; bilirubin rises in later stage
- positive anti-mitochondrial antibodies (AMA; 95% specificity and sensitivity)
- increased serum cholesterol (mild increase in LDL, larger increase in HDL)
  - may have: xanthelasmas, xanthomas
- liver biopsy confirms diagnosis and stages severity
- normal bile duct on MRCP rules out bile duct obstruction which can mimic PBC
- recently described “overlap” syndromes with autoimmune cholangitis, autoimmune hepatitis, sclerosing cholangitis

Clinical Course
- can be fatal, although not all asymptomatic patients show progression

Treatment
- treat with ursodiol (less frequently colchicine, methotrexate)
- cholestyramine (for pruritus and hypercholesterolemia)
- calcium and vitamin D for low bone density; bisphosphonates if osteoporosis severe
- monitor for thyroid disease
- liver transplant if disease severe, progressive

**Secondary Biliary Cirrhosis**

**Definition**
- cirrhosis from prolonged partial or total obstruction of major bile ducts

**Etiology**
- acquired: post-op strictures, chronic pancreatitis, sclerosing cholangitis, stone in bile duct
- congenital: cystic fibrosis (CF), congenital biliary atresia, choledochal cysts

**Diagnosis**
- cholangiography and liver biopsy

**Treatment**
- treat obstruction, give antibiotics for cholangitis prophylaxis

**Biliary Colic, Cholecystitis**

- see General Surgery, GS46

**Ascending Cholangitis**

- see General Surgery, GS48

**Definition**
- infection of the biliary tree

**Etiology**
- stasis in the biliary tract due to obstruction or stricture (usually from previous cholecystectomy)
- infection originates in the duodenum or spreads hematogenously from the portal vein
- bacteria
  - *E. coli*, *Klebsiella*, *Enterobacter*, *Enterococcus*
  - co-infection with *Bacteroides* and *Clostridia* can occur

**Signs and Symptoms**
- Charcot’s triad: fever, RUQ pain, jaundice (50-70%)
- Reynold’s Pentad in patients with suppurative cholangitis: fever, RUQ pain, jaundice, hypotension, altered mental status

**Diagnosis**
- increased WBC
- usually increased ALP and bilirubin, ALT variably elevated
- blood culture
- abdominal U/S: CBD dilation, stones

**Treatment**
- most important is drainage, ideally via ERCP, but if necessary by percutaneous biliary or surgical routes
- antibiotic therapy: broad spectrum to cover Gram-negatives, *Enterococcus*, and anaerobes (especially if CBD manipulation); no clear consensus on antibiotic choice but consider:
  - ampicillin + sulbactam or piperacillin/tazobactam
  - metronidazole + 3rd generation cephalosporin (e.g. ceftriaxone) or fluoroquinolone (e.g. ciprofloxacin or levofloxacin)
  - carbapenem monotherapy (e.g. imipenem or meropenem)

**Prognosis**
- good with effective drainage and antibiotics in mild to moderate cases
- high mortality (~50%) in patients with Reynold’s Pentad
Pancreatic Enzyme Abnormalities

Causes of Increased Serum Amylase

- pancreatic disease
  - pancreatic diseases: pancreatitis, pancreatic duct obstruction (e.g. ampullary cancer), pseudocyst, abscess, ascites, trauma, cancer
- non-pancreatic abdominal disease
  - biliary tract disease, bowel obstruction/ischemia, perforated or penetrating ulcer, ruptured ectopic pregnancy, aneurysm, chronic liver disease, peritonitis
- non-abdominal disease
  - cancer (lung, ovary, esophagus, etc.), salivary gland lesions, bulimia, renal transplant/insufficiency, burns, ketoacidosis
  - macroamylasemia

Causes of Increased Serum Lipase

- pancreatic disease: same as above
- non-pancreatic abdominal disease (mild elevations only): same as above
- non-abdominal disease
  - macrolipasemia
  - renal failure

Acute Pancreatitis

Etiology

Idiopathic: thought to be hypertensive sphincter or microlithiasis
Gallstones (45%)
Ethanol (35%)
Tumours: pancreas, ampulla, choledochocoele
Scorpion stings
Microbiological
  - bacterial: Mycoplasma, Campylobacter, TB, M. avium intracellulare, Legionella, leptospirosis
  - viral: mumps, rubella, varicella, viral hepatitis, CMV, EBV, HIV, Coxsackie virus, echovirus, adenovirus
  - parasites: ascariasis, clonorchiasis, echinococcosis
Autoimmune: SLE, polyarteritis nodosa (PAN), Crohn's
Surgery/trauma
  - manipulation of sphincter of Oddi (e.g. ERCP), post-cardiac surgery, blunt trauma to abdomen, penetrating peptic ulcer
Hyperlipidemia (TG >11.3 mmol/L; >1000 mg/dL), Hypercalcemia, Hypothermia
Emboli or Ischemia
Drugs/toxins
  - azathioprine, mercaptopurine, furosemide, estrogens, methyl dopa, H2-blockers, valproic acid, antibiotics, acetaminophen, salicylates, methanol, organophosphates, steroids (controversial)

Pathogenesis

- activation of proteolytic enzymes within pancreatic cells, starting with trypsin, leading to local and systemic inflammatory response
- in gallstone pancreatitis, this is due to mechanical obstruction of the pancreatic duct by stones
- in ethanol-related pancreatitis, pathogenesis is unknown
- in rare genetic diseases, mutations prevent the physiological breakdown of trypsin required normally to stop proteolysis (e.g. mutant trypsin in hereditary pancreatitis or mutation in SPINK 1 gene which normally inhibits activated trypsin); may be model for ethanol-related pancreatitis

Pathology

- mild (interstitial)
  - peri-pancreatic fat necrosis
  - interstitial edema
- severe (necrotic)
  - extensive peri-pancreatic and intra-pancreatic fat necrosis
  - parenchymal necrosis and hemorrhage → infection in 60%
  - release of toxic factors into systemic circulation and peritoneal space (causes multi-organ failure)
- severity of clinical features may not always correlate with pathology
• 3 phases:
  ▪ local inflammation + necrosis → hypovolemia
  ▪ systemic inflammation in multiple organs, especially in lungs, usually after IV fluids given → pulmonary edema
  ▪ local complications 2 wk after presentation → pancreatic sepsis/abscess

### Signs and Symptoms

- pain: epigastric, noncolicky, constant
- can raditate to back
- may improve when leaning forward (Inglefinger’s sign)
- tender rigid abdomen; guarding
- nausea and vomiting
- abdominal distention from paralytic ileus
- fever: chemical, not due to infection
- jaundice: compression or obstruction of bile duct
- Cullen/Grey-Turner’s signs
- tetany: transient hypocalcemia
- hypovolemic shock: can lead to renal failure
- acute respiratory distress syndrome
- coma

### Investigations

- increased serum pancreatic enzymes: amylase, lipase (more specific)
- ALT >150 specific for biliary cause
- increased WBC, glucose, low calcium
- imaging: CT most useful for diagnosis and prognosis
  - x-ray: “sentinel loop” (dilated proximal jejunum), calcification and “colon cut-off sign” (colonic spasm)
  - U/S: useful for evaluating biliary tree (67% sensitivity, 100% specificity)
  - CT scan with IV contrast: useful for diagnosis and prognosis because contrast seen only in viable pancreatic tissue, non-viable areas can be biopsied percutaneously to differentiate sterile from infected necrosis
  - ERCP or MRCP if cause uncertain, assess for duct stone, pancreatic or ampullary tumour, pancreas divisum

### Prognosis

- usually a benign, self-limiting course, single or recurrent
- occasionally severe leading to:
  ▪ shock
  ▪ pulmonary edema
  ▪ multi-organ dysfunction syndrome
  ▪ GI ulceration due to stress
  ▪ death
- mortality according to Ranson’s criteria (see sidebar)
  ▪ ≤2 criteria = <5% mortality
  ▪ 3–4 criteria = 15–20%
  ▪ 5–6 criteria = 40%
  ▪ ≥7 criteria = >99%
- multiple other prognostic indices available, more accurate than Ranson but difficult to remember (e.g. APACHE)

### Treatment

- goals (only supportive therapy available):
  (1) hemodynamic stability
  (2) analgesia
  (3) oxygen
  (4) stop progression of damage (difficult)
  (5) treat local and systemic complications
- antibiotics controversial except in documented infection (use cephalosporins, imipenem)
- aspirate necrotic areas of pancreas to diagnose infection; drain if infected
- IV fluids (crystalloid or colloid)
- beware third spacing of fluid, monitor urine output carefully
- NG suction (rests pancreas) if vomiting, stomach very dilated
- endoscopic sphincterotomy if severe gallstone pancreatitis (i.e. cholangitis or ongoing obstruction)
- nutritional support: nasojejunal feeding tube or TPN if cannot tolerate enteric feeds
- recent evidence supports nasogastric enteral (or oral if feasible) feeds
- no benefit: glucagon, atropine, aprotinin, H2-blockers, peritoneal lavage
- follow clinically and CT/ultrasound to exclude complications
- chief role of surgery is to drain fluid or excise necrotic tissue (necrosectomy) in the case of infected pancreatic necrosis (try to delay for >2 wk to allow demarcation between viable and necrotic tissue)

---

G45 Gastroenterology Pancreas Toronto Notes 2014

---

**Prophylactic Antibiotics Cannot Reduce Infected Pancreatic Necrosis and Mortality in Acute Necrotizing Pancreatitis: Evidence from a Meta-analysis of Randomized Controlled Trials**

**An J Gastroenterol 2008;103:104-110**

**Study Selection:** RCTs comparing antibiotics with placebo or no treatment.

**Results:** Seven trials (n = 463) were included. Antibiotics were not statistically superior to controls in reduction of infected necrosis and mortality.

**Conclusion:** Prophylactic antibiotics cannot reduce infected pancreatic necrosis and mortality in patients with acute necrotizing pancreatitis.

---

**Ranson’s Criteria: Prognostic Indicator of Mortality in Pancreatitis not due to Gallstones**

**At Admission**

- G: Blood Glucose >11 mmol/L (>200 mg/dL) (with no history of hyperglycemia)
- A: Age >55
- L: Serum LDH >350 IU/L
- W: WBC >6x10^9/L (60,000/mm^3)

**During First 48 h**

- C: Serum Calcium <2 mmol/L (<8 mEq/L)
- B: Base deficit >4 mmol/L (>4 mEq/L)
- S: Estimated fluid Sequestration >6 L

- ≥7 criteria present
- High mortality if ≥3 criteria present

---

**Increased Amylase**

- Sensitive, not specific

**Increased Lipase**

- Higher sensitivity and specificity
- Stays elevated longer

---

**Rep 2009;11:104-110**

**Increased Pancreatic Enzymes**

- Specific for biliary cause

**Increased Serum Lipase**

- Specific for biliary cause

---

**Infectious Complications of Necrotizing Pancreatitis**

- Pneumonia
- Peritonitis
- Sepsis

---

**Pancreatic Ulcers**

- Often diagnosed by CT scan

---

**Pancreatic Sepsis/Abscess**

- Common complications

---

**Prognosis of Necrotizing Pancreatitis**

- Mortality according to Ranson’s criteria

---

**Surgical Complications of Necrotizing Pancreatitis**

- Pancreatic ascites
- Pancreatic pseudocyst

---

**Management of Necrotizing Pancreatitis**

- Early operative intervention

---

**Prognostic Indices of Necrotizing Pancreatitis**

- Ranson’s Criteria
- GPR
- Rep 2009;11:104-110

---

**Incidence of Necrotizing Pancreatitis**

- 20% of patients with acute pancreatitis

---

**Epidemiology of Necrotizing Pancreatitis**

- More common in developed countries

---

**Risk Factors for Necrotizing Pancreatitis**

- Alcohol use
- Hyperlipidemia
- Diabetes mellitus

---

**Pathophysiology of Necrotizing Pancreatitis**

- Autodigestion of pancreas

---

**Pathology of Necrotizing Pancreatitis**

- Necrotic tissue
- Infected pancreatic necrosis

---

**Treatment of Necrotizing Pancreatitis**

- Conservative management

---

**Conclusion of Necrotizing Pancreatitis**

- Management remains challenging
Late Complications
- pseudocysts: follow if asymptomatic, drain if symptomatic or growing
  - drain: choice of endoscopic, percutaneous under radiological guidance, or surgical
- infected necrosis/abscesses: antibiotics + percutaneous drainage, endoscopic vs. surgical
- bleeding: (1) gastric varices if splenic vein thrombosis, (2) pseudoaneurysm of vessels in areas of necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged pancreas
- splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven, hazardous
- rare: diabetes, pancreatic duct damage

Chronic Pancreatitis

Definition
- irreversible damage to pancreas characterized by:
  1. pancreatic cell loss (from necrosis)
  2. inflammation
  3. fibrosis

Etiology/Pathophysiology
- alcohol (most common):
  - causes a larger proportion (>90%) of chronic pancreatitis than acute pancreatitis
  - changes composition of pancreatic juice (e.g. increases viscosity)
  - decreases pancreatic secretion of pancreatic stone protein (lithostathine) which normally solubilizes calcium salts
    - precipitation of calcium within pancreatic duct results in duct and gland destruction
  - toxic effect on acinar and duct cells – directly or via increasing free radicals
    - acinar cell injury leads to cytokine release, which stimulates pancreatic stellate cells to form collagen (leading to fibrosis)
  - varying degrees of ductular dilatation, strictures, protein plugs, calcification
  - no satisfactory theory to explain why only a minority of alcoholics develop pancreatitis
- unusual causes
  - cystic fibrosis
  - severe protein-calorie malnutrition
  - hereditary
  - idiopathic

Signs and Symptoms
- early stages:
  - recurrent attacks of severe abdominal pain (upper abdomen and back)
  - chronic painless pancreatitis: 10%
- late stages: occurs in 15% of patients
  - malabsorption syndrome when >90% of function is lost, steatorrhea
  - diabetes, calcification, jaundice, weight loss, pseudocyst, ascites, GI bleed

Investigations
- laboratory:
  - increase in serum glucose
  - increase in serum ALP, less commonly bilirubin (jaundice)
  - serum amylase and lipase usually normal
- AXR: looking for pancreatic calcifications
- U/S or CT: calcification, dilated pancreatic ducts, pseudocyst
- MRCP or ERCP: abnormalities of pancreatic ducts-narrowing and dilatation
- EUS: abnormalities of pancreatic parenchyma and pancreatic ducts
- secretin test: gold standard, measures exocrine function but difficult to perform, unpleasant for patient, expensive
- fecal pancreatic enzyme measurement (elastase-1, chymotrypsin) available only in selected centres

Management
- most common problem is pain, difficult to control
- general management:
  - total abstinence from alcohol
  - enzyme replacement may help pain by resting pancreas via negative feedback
  - analgesics
  - celiac ganglion blocks
  - time: pain decreases with time as pancreas "burns out"
- endoscopy: sphincterotomy, stent if duct dilated, remove stones from pancreatic duct
• surgery: drain pancreatic duct (pancreaticojejunostomy) if duct dilated (more effective than endoscopy); resect pancreas if duct contracted
• steatorrhea:
  ▪ pancreatic enzyme replacement
  ▪ restrict fat, increase carbohydrate and protein (may also decrease pain)
  ▪ neither endoscopy nor surgery can improve pancreatic function

**Autoimmune Pancreatitis**

• most commonly presents as a mimicker of pancreatic cancer (pancreatic mass detected because of jaundice & abdominal pain)

**Investigations**

• histology: lymphocyte and plasma cell infiltration of pancreas
• imaging: focal or diffuse enlargement of pancreas on CT or MRI, sausage shaped, low density rim around pancreas
• serology: increased serum IgG4
• other organs involvement: sialadenitis, retroperitoneal fibrosis, biliary duct narrowing, nephritis

**Treatment**

• responds to prednisone

---

**Clinical Nutrition**

**Determination of Nutritional Status**

• corrected weight loss [expressed as body mass index (kg/m²)] is most important parameter in assessing need for nutritional support

**Investigations**

• plasma proteins: albumin, pre-albumin (shorter half life than albumin), transferrin
  ▪ decrease may indicate decreased nutritional status or disease state
• thyroid-binding globulin, retinol-binding protein (may be too sensitive)
• anthropometry (e.g. triceps skinfold thickness), grip strength less often used

**Enteral Nutrition (EN)**

**Definition**

• enteral nutrition (tube feeding) is a way of providing food through a tube placed in the stomach or the small intestine
• choice of tubes: nasogastric (NG), nasojejunal (NJ), percutaneous endoscopic gastrostomy (G-tube), percutaneous endoscopic jejunostomy (J-tube) or tubes can be placed radiologically, surgically

**Indications**

• oral feeding inadequate or contraindicated

**Feeds**

• polymeric feeds contain whole protein, carbohydrate, fat as a liquid, with or without fibre
• elemental feeds contain protein as amino acids, carbohydrate as simple sugars, fat content low (therefore high osmolarity)
• specific diets: low carbohydrate/high fat solution for ventilated patients (carbohydrate has a high respiratory quotient so minimizes carbon dioxide production), high energy, low electrolyte solutions for dialysis patients

**Relative Contraindications**

• non-functioning gut (e.g. intestinal obstruction, enterocutaneous or enterocutaneous fistulae)
• uncontrolled diarrhea
• GI bleeding
Complications
- aspiration
- diarrhea
- refeeding syndrome (rare): carbohydrate can stimulate excessive insulin release, leading to cellular uptake and low serum levels of phosphate, magnesium, potassium
- overfeeding syndrome (rare): hypertonic dehydration, hyperglycemia, hypercapnea, azotemia (from excess protein)

Enteral Nutrition Advantages over Parenteral Nutrition
- far fewer serious complications (especially sepsis)
- nutritional requirements for enterally administered nutrition better understood
- can supply gut-specific fuels such as glutamine and short chain fatty acids
- nutrients in the intestinal lumen prevent atrophy of the gut and pancreas
- prevents gallstones by stimulating gallbladder motility
- much less expensive

Parenteral Nutrition (PN)

Definition
- parenteral nutrition is the practice of feeding a person intravenously, bypassing the usual process of eating and digestion

Indications
- short term (<1 mo)
  - whenever GI tract not functioning
    - only situations where PN has been well shown to increase survival are after bone marrow transplant and in short bowel syndrome, some evidence for benefit in gastric cancer, but often used in ICU, perioperatively and difficult to control sepsis
  - preoperative: only useful in severely malnourished (e.g. loss of >15% of pre-morbid weight, serum albumin <28 g/L or <2.8 g/dL), and only if given for ≥2 wk
  - renal failure: PN shown to increase rate of recovery; no increase in survival
  - liver disease: branched chain amino acids may shorten duration of encephalopathy; no increase in survival
  - IBD: PN closes fistulae and heals acute exacerbations of mucosal inflammation, but effect is transient (EN is equally effective)
  - some evidence for efficacy, but convincing data not available for:
    - radiation/chemotherapy-induced enteritis
    - AIDS with wasting diarrhea
    - severe acute pancreatitis
- long term (>1 mo): can be given at home
  - severe untreatable small bowel disease (e.g. radiation enteritis, extensive CD, high output fistulae)
  - following surgical resection of >70% of bowel (e.g. bowel infarction)
  - severe motility diseases (e.g. scleroderma affecting bowel)

Relative Contraindications
- functional GI tract for enteral nutrition
- active infection; at least until appropriate antibiotic coverage
- inadequate venous access; triple-lumen central venous lines usually prevent this problem
- unreliable patient or clinical setting

Complications of PN
- sepsis: most serious of the common complications
- mechanical pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
- metabolic: CHF, hyperglycemia, gallstones, cholestasis

Enteral versus Parenteral Nutrition for Acute Pancreatitis
Cochrane DB of Syst Rev 2010;1:CD002037

Purpose: Compare EN versus TPN on mortality, morbidity and hospital stay in patients with pancreatitis.
Study Selection: RCTs of TPN versus EN in pancreatitis.
Results: Eight trials (n=348) were included. Enteral nutrition decreases RR of death (0.50), multiple organ failure (0.55), infection (0.39) and other local complications (0.70). It also decreased hospital stay by 2.37 d.
Conclusion: EN reduces mortality, organ failure, infections and length of hospital stay in patients with pancreatitis.

Whenever possible, enteral nutrition is ALWAYS preferable over parenteral nutrition!

Acronyms

AAA: abdominal aortic aneurysm
ABG: arterial blood gas
ABI: ankle brachial index
APR: abdomino-perineal resection
BRBPR: bright red blood per rectum
CBD: common bile duct
CVA: costovertebral angle
CVP: central venous pressure
DIC: disseminated intravascular coagulation
DPL: diagnostic peritoneal lavage
EBL: estimated blood loss
EGD/EGD: esophagogastro-duodenoscopy
EUA: examination under anesthesia
ERCP: endoscopic retrograde cholangiopancreatography
ERCP: endoscopic ultrasound
FAST: focused abdominal sonogram for trauma
FNA: fine needle aspiration
FOBT: fecal occult blood test
Gastroesophageal reflux disease
Gerard’s syndrome
HNPCC: hereditary non-polyposis colorectal cancer
HDGC: hereditary diffuse gastric carcinoma
I&D: incision and drainage
IAR: low anterior resection
I&D: incision and drainage
MRCP: magnetic resonance cholangiography
NGT: nasogastric tube
OBJ: oesophageo-gastro-duodenoscopy
POD: postoperative day
PTC: percutaneous transhepatic cholangiography
SBO: small bowel obstruction
SIADH: syndrome of inappropriate anti-diuretic hormone
TED: thromboembolic deterrent
TEE: transesophageal echocardiogram
TEE: thoracic echocardiogram
UGIB: upper GI bleed
VATS: video-assisted thoracic surgery

Layers from Superficial to Deep

- skin (epidermis, dermis, subcutaneous fat)
- superficial fascia
  - Camper’s fascia (fatty) → Dartos
  - Scarpa’s fascia (membranous) → Colles’ superficial perineal fascia
- muscle (see Figure 2 and Figure 3)
  - external oblique → inguinal ligament → external spermatic fascia → fascia lata
  - internal oblique → cremasteric muscle/fascia
  - transversus abdominis → posterior inguinal wall
  - transversalis fascia → internal spermatic fascia
  - preperitoneal fat
  - peritoneum → tunica vaginalis
- at midline
  - rectus abdominus muscle: in rectus sheath, divided by linea alba
- above arcuate line (semicircular line of Douglas), which is midway between symphysis pubis and umbilicus
  - anterior rectus sheath = external oblique aponeurosis and anterior leaf of internal oblique aponeurosis
  - posterior rectus sheath = posterior leaf of internal oblique aponeurosis and transversus muscle aponeurosis
- below arcuate line
  - anterior rectus sheath = aponeurosis of external, internal oblique, transversus muscles
  - posterior rectus sheath = transversalis fascia
- arteries: superior epigastric (branch of internal thoracic), inferior epigastric (branch of external iliac); both arteries Anastomose and lie behind the rectus muscle

Basic Anatomy Review

Figure 1. Abdominal incisions

- Paramedian
- McBurney’s
- Pfannenstiel
- Lower midline
- Access to pelvic organs, sigmoid colon, and rectum

Figure 2. Continuity of the abdominal wall with layers of the scrotum and spermatic cord
Figure 3. Midline cross-section of abdominal wall

Figure 4. Blood supply to the GI tract

Venous Flow

Porto-systemic anastomoses:
1. Esophageal branches of left gastric vein with esophageal veins
2. Paraumbilical veins with subcutaneous veins of anterior abdominal wall
3. Superior rectal vein with middle and inferior rectal veins

Figure 5. Venous drainage of the GI tract

### Genitourinary

| Abdominal wall hernoma/abscess |
| Psoas abscess |

### Extraperitoneal

| Abdominal wall hernoma/abscess |
| Psoas abscess |

### Referred Pain

- Biliary colic: to right shoulder or scalpula
- Renal colic: to groin
- Appendicitis: periumbilical to right lower quadrant (RLQ)
- Pancreatitis: to back
- Ruptured aortic aneurysm: to back or flank
- Perforated ulcer: to RLQ (right paracolic gutter)

### Localization of Pain

- Most digestive tract pain is perceived in the midline because of bilaterally symmetric innervation. Kidney, ureter, ovary, or somatically innervated structures are more likely to cause lateralized pain.

### Types of Peritonitis

- Primary peritonitis: spontaneous without clear etiology
- Secondary peritonitis: due to a perforated viscus
- Tertiary peritonitis: recurrent secondary peritonitis more often with resistant organisms

### Key Tests for Specific Diagnosis

- ALP, ALT, AST, bilirubin
- Amylase/lipase
- Urinalysis
- t-HCG (in women of childbearing age)
- Troponins
- Lactate

### Key Tests for OR Preparation

- CBC, electrolytes, BUN, creatinine, glucose
- CXR + ECG

### Pancreatitis can look like a surgical abdomen, but is rarely an indication for immediate laparotomy.
## Abdominal Mass

## GI Bleeding

- see Gastroenterology, G25

### Indications for Surgery

- failure of medical management
- hemodynamic instability despite vigorous resuscitation
- recurrent hemorrhage after initial stabilization procedures with up to two attempts of endoscopic hemostasis
- hypovolemic shock
- prolonged bleeding with transfusion requirement >3 units/d

### Surgical Management of GI Bleeding

- upper GI bleeding:
  - bleeding from a source proximal to the ligament of Treitz
  - often presents with hematemesis and melena unless very brisk (then can present with hematochezia, hypotension, tachycardia)
  - initial management with endoscopy; if fails, then consider surgery
  - note: PUD accounts for approximately 55% of severe UGI bleeding
- lower GI bleeding:
  - bleeding from a source distal to the ligament of Treitz
  - often presents with BRBPR unless proximal to transverse colon
  - may occasionally present with melena
  - initial management with colonoscopy to detect and potentially stop source of bleeding
  - angiography, RBC scan to determine source as indicated
  - surgical intervention if no source found – obscure bleed

### Table 3. Differential Diagnosis of GI Bleeding

### Indications for Urgent Operation

- IHOP: Ischemia, Hemorrhage, Obstruction, Perforation

### Transfusion Strategies for Acute Upper Gastrointestinal Bleeding

*NEJM 2013;368:11-21*

Recent study by Villanueva et. al, demonstrates that a restrictive transfusion strategy significantly improves outcomes in patients with acute upper GI bleeding, compared to a liberal transfusion strategy. Refer to study for details.

Biochemical Signs for Differentiating Jaundice

Hepatocellular: Elevated bilirubin + elevated ALT/AST
Cholestatic: Elevated bilirubin + elevated ALP/GGT + duct dilatation upon biliary U/S
Hemolysis: ↓ haptoglobin ↑ LDH

Note: cholestatic jaundice is usually surgical.

In patients with liver disease and an acute abdomen, spontaneous bacterial peritonitis must be ruled out.

Preoperative Preparations

Considerations
- informed consent (see Ethical, Legal and Organizational Aspects of Medicine, ELOAM5)
- screening questionnaire to assess important potential risk factors such as age, exercise capacity, and medication use
- consults: anesthesia, medicine, cardiology as indicated
- NPO ≥ 6 h prior, AAT (activity as tolerated), VSR (vital signs routine)
- IV – balanced crystalloid at maintenance rate (4:2:1 rule → roughly 100-125 cc/h): normal saline or Ringer’s lactate; bolus to catch up on estimated losses including losses from bowel prep
- appropriate use of fluids perioperatively decreases risk of cardiorespiratory complications
- patient’s regular medications including prednisone: consider pre-op stress dose if prednisone with β-blocker used in past year
- prophylactic antibiotics depending on wound class (within 1 h prior to incision): usually cefazolin (Ancef®) ± metronidazole (Flagyl®)
- bowel prep: cleans out bowel and decreases bacterial population
- oral cathartic (e.g. fleet Phosphosoda®) starting previous day
- in selected cases; current evidence does not support routine use
- consider DVT prophylaxis for all inpatient surgery (heparin)

Best Practice in General Surgery (BPIGS)
http://www.bpigs.ca/
BPIGS is a University of Toronto initiative with the goal of standardizing care in general surgery. This link contains EBM based guidelines which have been implemented by consensus within all Toronto teaching hospitals. This is a highly recommended source for the most up to date pre-operative and general treatment guidelines.
preoperative preperations/surgical complications

- do not hold heparin prior to surgery unless epidural is expected
- hold ASA x 1 wk pre-op
- smoking cessation x 6 wk pre-op can significantly decrease post-op complications

investigations

- blood components: group and screen or cross and type depending on procedure
- CBC, electrolytes, BUN, creatinine
- INR/PT, PTT
- ABGs if predisposed to respiratory insufficiency
- CXR (PA and lateral) if >50 yr old or previously abnormal within past 6 mo
- ECG if >50 yr old or as indicated by history
- β-HCG testing in all women of reproductive age

drains

- nasogastric (NG) tube:
  - indications: gastric decompression, analysis of gastric contents, irrigation/dilution of gastric contents, feeding (only if necessary due to risk of aspiration → naso-jejunal tube preferable)
  - contraindications: suspected basal skull fracture, obstruction of nasal passages due to trauma
- Foley catheter with urometer:
  - indications: to accurately monitor urine output, decompression of bladder, relieve obstruction, rapidly expanding suprapubic mass
  - contraindications: suspected urethral injury, difficult insertion of catheter

surgical complications

postoperative fever

- fever does not necessarily imply infection particularly in the first 24-48 h post-op
- fever may not be present or is blunted if patient is receiving chemotherapy, glucocorticoids or immunosuppression
- timing of fever may help identify cause
  - hours after surgery – POD #1 (immediate):
    - inflammatory reaction in response to trauma from surgery
    - reaction to blood products received during surgery
    - malignant hyperthermia
  - POD #1-2 (acute):
    - atelectasis (most common cause of fever on POD #1)
    - early wound infection (especially Clostridium, Group A Streptococcus – feel for crepitus and look for “dishwater” drainage)
    - aspiration pneumonitis
    - other: Addisonian crisis, thyroid storm, transfusion reaction
  - POD #3-7 (subacute): infections more likely
    - UTI, surgical site infection, IV site/line infection, septic thrombophlebitis, leakage at bowel anastomosis (tachycardia, hypotension, oliguria, abdominal pain)
  - POD #8+ (delayed):
    - intra-abdominal abscess, DVT/PE (can be anytime post-op, most commonly POD #8-10), drug fever
    - other: cholecystitis, peri-rectal abscess, URTI, infected seroma/biloma/hematoma, parotitis, C. difficile colitis, endocarditis

Treatment

- treat primary cause
- antipyrexia (e.g. acetaminophen)

wound/incisional complications

wound care

- can shower POD #2-3 after epithelialization of wound
- dressings can be removed POD #2 and left uncovered if dry
- examine wound if wet dressing, signs of infection (fever, tachycardia, pain)
- skin sutures and staples can be removed POD #7-10:
  - exceptions: incision crosses crease (groin), closed under tension, in extremities (hand) or patient factors (elderly, corticosteroid use, immunosuppressed) removed POD #14, earlier if signs of infection
- negative pressure dressings consist of foam and suction, promote granulation
  - ideal for large (grafted sites) or non-healing wounds (irradiated skin, ulcer)
DRAINS
- sometimes placed intra-operatively to prevent fluid accumulation (blood, pus, serum, bile, urine)
- can be used to assess quantity of third space fluid accumulation post-operatively
- potential route of infection, bring out through separate incision (vs. operative wound) to decrease risk of wound infection and remove as soon as possible
- types of drains
  - open (Penrose), higher risk of infection
  - closed (Jackson-Pratt, hemovac) connected to suction
  - pump (Davol) suction with airflow system to prevent obstruction
- monitor drain outputs daily
- drains should be removed once drainage is minimal (usually less than 30-50 cc/24 h)
- evidence does not support routine post-operative drainage of abdominal cavity

SURGICAL SITE INFECTION

Etiology
- S. aureus, E. coli, Enterococcus, Streptococcus spp., Clostridium spp.

Risk Factors
- type of procedure:
  - clean (elective, not emergent, not traumatic, no acute inflammation, resp/GI/biliary/GU tracts not entered): <1.5%
  - clean-contaminated (elective entering of resp/GI/biliary/GU tracts): <3%
  - contaminated (nonpurulent inflammation, gross spillage from GI, entry into biliary or GU tracts with infected bile/urine, penetrating trauma <4 h old): 5%
  - dirty (purulent inflammation, pre-op perforation of resp/GI/biliary/GU tracts, penetrating trauma >4 h old): ~33-50%
  - increased risk with procedures >2 h long, use of drains
- patient characteristics:
  - age, DM, steroids, immunosuppression, obesity, burn, malnutrition, patient with other infections, traumatic wound, radiation, chemotherapy
- other factors:
  - prolonged preoperative hospitalization, reduced blood flow, break in sterile technique, multiple antibiotics, hematoma, seroma, foreign bodies (drains, sutures, grafts), skin preparation, hypoxemia, hypothermia

Clinical Presentation
- typically fever POD #3-6 (Streptococcus and Clostridium can present in 24 h)
- pain, blanchable wound erythema, induration, frank pus or purulosanguinous discharge, warmth
- complications: fistula, sinus tracts, sepsis, abscess, suppressed wound healing, superinfection, spreading infection to myonecrosis or fascial necrosis (necrotizing fasciitis), wound dehiscence, evisceration, hernia

Prophylaxis
- used to reduce the chance of surgical site infections
- pre-op antibiotics for most surgeries (cefazolin ± metronidazole or if β-lactam allergy, clindamycin ± gentamycin):
  - within 1 h pre-incision; can re-dose at 1-2 half lives (~q4-8h) in the OR
  - not required for low risk elective cholecystectomy, hemorrhoidectomy, fistulotomy, sphincterotomy for fissure
- generally no need to continue prophylactic antibiotics postoperatively, reserve post-operative antibiotics for treatment of suspected or documented intra-abdominal infection
- normothermia (maintain patient temperature 36-38°C during OR)
- hyperoxygenation (consider FiO₂ of 80% in OR)
- chlorhexidine-alcohol wash of surgical site
- hair removal should not be performed unless necessary; if so, clipping superior to shaving
- consider delayed primary closure of incision for contaminated wounds

Treatment
- examination of the wound: inspect, compress adjacent areas, swab drainage for C&S and Gram stain
- re-open affected part of incision, pack, heal by secondary intention
- antibiotics and débridement of erythema only if cellulitis or immunodeficiency
- debride necrotic and non-viable tissue
WOUND HEMORRHAGE/HEMATOMA
• secondary to inadequate surgical control of hemostasis

Risk Factors
• anticoagulant therapy, coagulopathies, thrombocytopenia, DIC, severe liver disease, myeloproliferative disorders, severe arterial hypertension, severe cough
• more common with transverse incisions through muscle

Clinical Features
• pain, swelling, discolouration of wound edges, leakage
• rapidly expanding neck hematoma can compromise airway and is a surgical emergency

Treatment
• pressure dressing
• open drainage ± wound packing (large hematoma only)
• if significant bleeding, may need to re-operate to find source (often do not find a discrete vessel)

SEROMA
• fluid collection other than pus or blood
• secondary to transection of lymph vessels
• delays healing
• increased infection risk

Treatment
• pressure dressing ± needle drainage
• if significant may need to re-operate

WOUND DEHISCENCE
• disruption of fascial layer, abdominal contents contained by skin only
• 95% caused by intact suture tearing through fascia

Clinical Features
• typically POD #1-3, most common presentation sign is serosanguinous drainage from wound, ± evisceration (disruption of all abdominal layers and extrusion of abdominal contents – mortality of 15%)
• palpation of wound edge: should normally feel a “healing ridge” from abdominal wall closure (raised area of tissue under incision)

Risk Factors
• local: technical failure of closure, increased intra-abdominal pressure (e.g. COPD, ileus, bowel obstruction), hematoma, infection, poor blood supply, radiation, patient not fully paralyzed while closing
• systemic: smoking, malnutrition (hypalbuminemia, vitamin C deficiency), connective tissue diseases, immunosuppression, pulmonary disease, ascites, poor nutrition, steroids, chemotherapy, obesity, other (e.g. age, sepsis, uremia)
• diabetes mellitus alone is not a risk factor

Treatment
• place moist dressing over wound with binder around abdomen and transfer to OR
• may consider conservative management with debridement of facial and/or skin margins
• evisceration is a surgical emergency: take patient for operative closure, use slowly absorbable suture ± retention sutures

URINARY RETENTION
• may occur after any operation with general anesthesia or spinal anesthesia
• more likely in older males with history of benign prostatic hyperplasia, patients on anticholinergics

Clinical Presentation
• abdominal discomfort, palpable bladder, overflow incontinence, post-void residual urine volume >100 mL

Treatment
• Foley catheter to rest bladder, then trial of voiding
OLIGURIA/ANURIA (see Nephrology, NP33)

**Etiology**
- pre-renal vs. renal vs. post-renal:
  - most common post-op cause is pre-renal ± ischemic ATN
  - external fluid loss: hemorrhage, dehydration, diarrhea
  - internal fluid loss: third-spacing due to bowel obstruction, pancreatitis

**Clinical Presentation**
- urine output <0.5 cc/kg/h, increasing Cr, increasing BUN

**Treatment**
- according to underlying cause; fluid deficit is treated with crystalloid (NS or RL)

---

### Postoperative Dyspnea

- see Respiratory Complications below and Cardiac Complications, GS11

**Etiology**
- respiratory: atelectasis, pneumonia, pulmonary embolus (PE), acute respiratory distress syndrome (ARDS), asthma, pleural effusion
- cardiac: MI, arrhythmia, CHF
- inadequate pain control

---

### Respiratory Complications

#### ATELECTASIS
- comprises 90% of post-op pulmonary complications

**Clinical Features**
- low-grade fever on POD #1, tachycardia, crackles, decreased breath sounds, bronchial breathing, tachypnea

**Risk Factors**
- COPD, smoking, obesity, elderly persons
- upper abdominal/thoracic surgery, oversedation, significant post-op pain, poor inspiratory effort

**Treatment**
- pre-operative prophylaxis
  - smoking cessation (best if >8 wk pre-op)
- postoperative prophylaxis
  - incentive spirometry, deep breathing exercise, chest physiotherapy, intermittent positive-pressure breathing
  - selective nasogastric tube decompression after abdominal surgery
  - short-acting neuromuscular blocking agents
  - minimize use of respiratory depressive drug, good pain control, early ambulation

---

#### PNEUMONIA/PNEUMONITIS
- may be secondary to aspiration of gastric contents during anesthetic induction or extubation, causing a chemical pneumonitis

**Risk Factors**
- aspiration: general anesthetic, decreased LOC, GERD, full stomach, bowel/gastric outlet obstruction + non-functioning NG tube, pregnancy, seizure disorder
- non-aspiration: atelectasis, immobility, pre-existing respiratory disease

**Clinical Features**
- productive cough, fever
- tachycardia, cyanosis, respiratory failure, decreased LOC
- CXR: pulmonary infiltrate

**Treatment**
- prophylaxis: see atelectasis prophylaxis, pre-op NPO/NG tube, rapid sequence anesthetic induction
- immediate removal of debris and fluid from airway
- consider endotracheal intubation and flexible bronchoscopic aspiration
- IV antibiotics to cover oral nosocomial aerobes and anaerobes (e.g. ceftriaxone, metronidazole)
PULMONARY EMBOLUS (see Respirology, R17)

Clinical Features
- unilateral leg swelling and pain (DVT as a source of PE), sudden onset SOB, tachycardia, fever
- most commonly POD #8-10, but can occur anytime post-op

Treatment
- IV heparin, long term warfarin (INR = 2-3) for 3 mo
- Greenfield (IVC) filter if contraindications to anticoagulation
- prophylaxis: subcutaneous heparin (3000 units bid) or LMWH, compression stockings (T.E.D. Hose)

PULMONARY EDEMA

Etiology
- cardiogenic vs. noncardiogenic
- circulatory overload: excess volume replacement, LV failure, shift of fluid from peripheral to pulmonary vascular bed, negative airway pressure, alveolar injury due to toxins (e.g. ARDS)
- more common with pre-existing cardiac disease
- negative pressure pulmonary edema due to inspiratory efforts against a closed glottis upon awakening from general anaesthesia

Clinical Features
- shortness of breath, crackles at lung bases, CXR abnormal

Treatment (LMNOP)
- L
  - Lasix
- M
  - Morphine (decreases symptoms of dyspnea, venodilator and afterload reduction)
- N
  - Nitrates (venodilator)
- O
  - Oxygen + non-invasive ventilation
- P
  - Position (sit patient up)

RESPIRATORY FAILURE

Clinical Features
- dyspnea, cyanosis, evidence of obstructive lung disease
- earliest manifestations – tachypnea and hypoxemia (RR >25, pO\textsubscript{2} <60)
- pulmonary edema, unexplained decrease in SaO\textsubscript{2}

Treatment
- ABCs, O\textsubscript{2}, ± intubation
- bronchodilators, diuretics to treat CHF
- adequate blood pressure to maintain pulmonary perfusion
- if these measures fail to keep PaO\textsubscript{2} >60, consider acute respiratory distress syndrome (ARDS)

Cardiac Complications

- abnormal ECGs common in post-op period (compare to pre-op ECG)
- common arrhythmias: supraventricular tachycardia (SVT), atrial fibrillation (secondary to fluid overload, PE, MI)

MYOCARDIAL INFARCTION (MI)

- see Cardiology and Cardiovascular Surgery, C24
- surgery increases risk of MI
- incidence:
  - 0.5% in previously asymptomatic men >50 yr old
  - 40-fold increase in men >50 yr old with previous MI

Risk Factors
- pre-op hypertension, CHF
- previous MI (highest risk ≤6 mo, but risk never returns to baseline)
- increased age
- intra-operative hypotension
- operations >3 h
- angina

Clinical Features
- majority of cases on day of operation or POD #3-4 (shifting of third space fluid back into intravascular compartment)
- often silent without chest pain, may only present with new-onset CHF (dyspnea), arrhythmias, hypotension
Intra-abdominal Abscess

Definition
- collection of pus walled-off from rest of peritoneal cavity by inflammatory adhesions and viscera

Etiology
- usually polymicrobial: Gram-negative bacteria, anaerobes
  - consider Gram-positives if coexisting cellulitis

Risk Factors
- emergency, contaminated OR
- GI surgery with anastomoses
- poor healing risk factors (DM, poor nutrition, etc.)
- may occur POD #3 after laparotomy when third space fluid re-distribution occurs

Clinical Features
- persistent spiking fever, dull pain, weight loss
- mass difficult to palpate
- peritoneal signs if abscess perforation and secondary peritonitis
- leukocytosis or leukopenia (immunocompromised, elderly)
- co-existing effusion (pleural effusion with subphrenic abscess)
- common sites: pelvis, Morrison's pouch (space between kidney and liver), subphrenic, paracolic gutters, lesser sac, peri-appendiceal, post-surgical anastomosis, diverticular, psoas

Investigations
- CBC, blood cultures x2
- CT ± water-soluble contrast
- DRE (pelvic abscess)

Treatment
- eradication (preferred), laparoscopy, open drainage
- subsequent antibiotic coverage, ciprofloxacin (Cipro®) + metronidazole (Flagyl®)

Paralytic Ileus
- see Bowel Obstruction, GS24

Delirium
- see Psychiatry, PS19 and Neurology, N17

Thoracic Surgery

Hiatus Hernia

![Types of hiatus hernia](image)

Figure 6. Types of hiatus hernia
SLIDING HIATUS HERNIA (Type I) (see Figure 6)
• herniation of both the stomach and the gastroesophageal (GE) junction into thorax
• 90% of esophageal hernias

Risk Factors
• age
• increased intra-abdominal pressure (e.g. obesity, pregnancy, coughing, heavy lifting)
• smoking

Clinical Features
• majority are asymptomatic
• larger hernias frequently associated with GERD due to decreased competence of GE junction

Complications
• most common complication is GERD
• other complications are rare and are related to reflux:
  • esophagitis (dysphagia, heartburn)
  • consequences of esophagitis (peptic stricture, Barrett’s esophagus, esophageal carcinoma)
  • extra-esophageal complications (pneumonitis/pneumonia, asthma, cough, laryngitis)

Investigations
• CXR, barium swallow, endoscopy, or esophageal manometry (technique for measuring LES pressure)
• 24-h esophageal pH monitoring to quantify reflux
• gastroscopy with biopsy to document type and extent of tissue damage and rule out esophagitis, Barrett’s esophagus and cancer

Treatment
• lifestyle modification:
  • stop smoking, weight loss, elevate head of bed, no meals <3 h prior to sleeping, smaller and more frequent meals, avoid alcohol, coffee, mint and fat
• medical:
  • antacid, H2-antagonist, proton pump inhibitor, prokinetic agent
• surgical (<15%):
  • if failure of medical therapy, esophageal stricture, severe nocturnal aspiration, Barrett’s esophagus
  • anti-reflux procedure (usually laparoscopic) e.g. Nissen fundoplication
    • fundus of stomach is wrapped around the lower esophagus and sutured in place
    • 90% success rate

PARAESOPHAGEAL HIATUS HERNIA (Type II) (see Figure 6)
• herniation of all or part of the stomach through the esophageal hiatus into the thorax with an undisplaced GE junction
• least common esophageal hernia (<10%)

Clinical Features
• usually asymptomatic due to normal GE junction
• pressure sensation in lower chest, dysphagia

Complications
• hemorrhage, incarceration, strangulation, obstruction, gastric stasis ulcer

Treatment
• surgery to prevent severe complications:
  • reduce hernia and excise hernia sac, repair defect at hiatus, and anti-reflux procedure (e.g. Nissen fundoplication)
  • may consider suturing stomach to anterior abdominal wall (gastropexy)
  • in very elderly patients at high surgical risk consider PEG (percutaneous endoscopic gastrostomy)

MIXED HIATUS HERNIA (Type III)
• combination of Types I and II

TYPE IV HERNIA
• herniation of other abdominal organs into thorax: colon, spleen, small bowel

Differential Diagnosis of Hiatus Hernia

Esophageal Perforation

Etiology
• iatrogenic (most common):
  ▪ endoscopic, dilatation, biopsy, intubation, operative, NG tube placement
• barogenic:
  ▪ trauma
  ▪ repeated, forceful vomiting (Boerhaave’s syndrome)
  ▪ other: convulsions, defecation, labour (rare)
• ingestion injury:
  ▪ foreign body, corrosive substance
  ▪ carcinoma

Clinical Features
• neck or chest pain
• fever, tachycardia, hypotension, dyspnea, respiratory compromise
• subcutaneous emphysema, pneumothorax, hematemesis

Investigations
• CXR: pneumothorax, pneumomediastinum, pleural effusion, subdiaphragmatic air
• CT chest: widened mediastinum, pneumomediastinum
• contrast swallow (water-soluble then thin barium): contrast extravasation

Treatment
• supportive if rupture is contained:
  ▪ NPO, vigorous fluid resuscitation, broad-spectrum antibiotics, possible percutaneous drainage
• surgical:
  ▪ <24 h
    ▪ primary closure of a healthy esophagus or resection of diseased esophagus
  ▪ >24 h or non-viable wound edges
    ▪ diversion and exclusion followed by delayed reconstruction (i.e. esophagostomy proximally, close esophagus distally, gastrostomy/jejunostomy for decompression/feeding)

Complications
• sepsis, abscess, fistula, empyema, mediastinitis, death
• post-op esophageal leak
• mortality 10-50% dependent on timing of diagnosis

Esophageal Carcinoma

Epidemiology
• M:F = 3:1
• onset 50-60 yr of age
• upper (20-33%), middle (33%), lower (33-50%)
• main types:
  ▪ most common worldwide: squamous cell carcinoma (SCC) in upper 2/3 of esophagus
  ▪ most common in western countries: adenocarcinoma in distal 1/3 of esophagus

Risk Factors
• geographic variation in incidence
• SCC:
  ▪ underlying esophageal disease such as strictures, diverticula, achalasia
  ▪ more common in patients from Asia
• adenocarcinoma:
  ▪ Barrett’s esophagus (most important), smoking, obesity (increased reflux), GERD

Clinical Features
• frequently asymptomatic: late presentation
• progressive dysphagia (mechanical): first solids then liquids
• odynophagia then constant pain
• constitutional symptoms
• regurgitation and aspiration (aspiration pneumonia)
• hematemesis, anemia
• tracheoesophageal or bronchoesophageal fistula
• direct, hematogenous or lymphatic spread:
  ▪ trachea (coughing), recurrent laryngeal nerves (hoarseness, vocal paralysis), aortic, liver, lung, bone, celiac and mediastinal nodes
Investigations
- barium swallow: shows narrowing – suggestive but not diagnostic
- esophagoscopy: biopsy and assess resectability
- endoscopic ultrasound (EUS):
  - visualize local disease
  - regional nodal involvement (most accurate way to stage the cancer)
- bronchoscopy ± thoracoscopy:
  - rule out airway invasion in tumours of the upper and mid esophagus
- CT chest/abdomen
- full metastatic workup (CXR, bone scan, CT-head/CAP, LTFs, etc.)

Treatment
- if present with distant metastatic disease
  - treat with systemic therapy and treat symptoms (esophageal stent)
- if locally advanced (locally invasive disease or nodal disease on CT or EUS):
  - multimodal therapy:
    - concurrent external beam radiation and chemotherapy (cisplatin and 5-FU)
    - possibility of curative esophagectomy after chemoradiation if disease responds well
    - if unable to tolerate multimodal therapy or if highly advanced disease, consider palliative resection, brachytherapy, or endoscopic dilatation/stenting/laser ablation for palliation
- if early stage (non-transmural and without evidence of nodal disease):
  - esophagectomy (transhiatal or trans-hiatal approach) and lymphadenectomy
  - anastomosis in chest or neck
  - stomach most often used for reconstruction; may also use colon
  - neoadjuvant chemotherapy and radiation are controversial
  - adjuvant chemotherapy ± radiation usually recommended for post-op node-positive disease

Prognosis
- prognosis usually poor because presentation is usually at advanced stage

OTHER DISORDERS
- esophageal varices (see Gastroenterology, G26)
- Mallory-Weiss tear (see Gastroenterology, G27)

Chest Wall

CONGENITAL ABNORMALITIES
- pectus excavatum, pectus carinatum, sternal fissures
- surgery for cosmesis, psychosocial factors, respiratory or cardiovascular insufficiency (uncommon)

THORACIC OUTLET SYNDROME
- impingement of subclavian vessels and brachial plexus nerve trunk

Etiology
- congenital: cervical rib
- trauma
- degenerative: osteoporosis, arthritis

Clinical Features
- neurogenic: ulnar and median nerve motor and sensory deficit
- arterial: fatigue, weakness, coldness, ischemic pain, paresthesia
- venous: edema, venous distention, collateral formation, cyanosis

Treatment
- conservative (50-90%)
  - physiotherapy, posture and behaviour modification
- surgical: if conservative treatment fails, removal of first or cervical rib (if applicable)

TUMOURS
- benign: fibrous dysplasia, eosinophilic granuloma, osteochondroma
- malignant: fibrosarcoma, chondrosarcoma, osteogenic sarcoma, Ewing's sarcoma, myeloma
**Pleura, Lung, and Mediastinum**

- see *Respirology*, R20

**Tube Thoracostomy**

**Indications**
- to drain abnormal large-volume air or fluid collections in the pleural space
  - hemothorax, chylothorax, empyema
  - pneumothorax, if:
    - large or progressive
    - patient is on mechanical ventilation
    - bronchopleural fistula
    - tension pneumothorax
- to facilitate pleurodesis:
  - i.e. obliteration of the pleural space by instilling talc or doxycycline to cause fibrosis and adherence of parietal and visceral pleura
  - indicated for recurrent pleural effusions (often malignant)
- for long-term drainage of malignant effusions

**Complications**
- overall complications are rare (1-3%)
- malposition (most common complication), especially by inexperienced operators:
  - tubes may dissect along the external chest wall, or may be placed below the diaphragm
- bleeding (anticoagulation is a relative contraindication)
- local infection, empyema
- perforation of lung parenchyma
- risk of re-expansion pulmonary edema when large volumes of air or fluid are drawn off quickly (>1.0-1.5 L)

**Lung Transplantation**

**Conditions Leading to Transplantation**
- chronic obstructive pulmonary disease (COPD), emphysema due to α-1 antitrypsin deficiency
- cystic fibrosis (CF)
- idiopathic interstitial pneumonias: idiopathic pulmonary fibrosis (IPF), nonspecific interstitial pneumonitis
- idiopathic pulmonary arterial hypertension (IPAH), secondary pulmonary hypertension
- Eisenmenger’s syndrome
- sarcoidosis, lymphangioleiomyomatosis, pulmonary Langerhan’s cell histiocytosis

**Clinical Indications**
- transplantation should be considered for patients with advanced lung disease refractory to maximal medical or surgical therapy
- patients who are symptomatic during activities of daily living and limited expected survival over the next 2 yr

**Criteria for Transplantation**
- lung allocation score based on: 1) post-transplant survival measure, and 2) waiting list urgency measure
- transplant benefit = post-transplant survival (days) – waitlist survival (days)

**Contraindications**
- uncontrolled or untreatable pulmonary or extrapulmonary infection
- malignancy in the last 2 yr
- advanced cardiopulmonary disease
- significant chest wall/spinal deformity
- active cigarette smoking
- HIV infection, ongoing HBV or HCV infections

**Post-op Complications**
- primary graft dysfunction: main cause is ischemia-reperfusion injury, graded by PaO2/FiO2 ratio and CXR findings
- airway anastomotic complications (focal infection, bronchial necrosis and dehiscence, excess granulation tissue, tracheobronchomalacia, stenosis, fistula)
- chronic graft dysfunction: bronchiolitis obliterans syndrome
• infectious complications (bacterial, fungal, CMV, community-acquired respiratory viruses, mycobacteria)
• malignancy (non-melanoma skin cancer, post-transplant lymphoproliferative disease, colon, breast, Kaposis sarcoma, bladder)

Prognosis
• median survival for all adult recipients: 5.4 yr
• 1 yr survival: COPD > IPF > IPAH
• 10 yr survival: CF, α-1 antitrypsin deficiency > IPAH > COPD, IPF

Chronic Obstructive Pulmonary Disease

• see Respirology, R8

Treatment
• indications for surgical management:
  ▪ dyspnea despite maximal medical therapy and pulmonary rehabilitation
  ▪ CT showing hyperinflation and heterogeneously distributed emphysema predominant in the upper lung zone
  ▪ may be used as a bridging procedure to lung transplantation
• contraindications:
  ▪ age >75, cigarette smoking within the prior 6 mo, higher risk of surgical mortality
  ▪ homogeneously distributed emphysematous changes without areas of preserved lung tissue
  ▪ DLCO <20% of predicted, PaCO2 >60 mm Hg, PaO2 <45 mmHg
• surgical procedures:
  ▪ lung volume reduction surgery (LVRS): wedge excision of emphysematous tissue
  ▪ bilateral or unilateral, thoracotomy or VATS

Complications of Treatment
• air leak: may require reintubation and mechanical ventilation
• arrhythmias, pneumonia

Prognosis
• total mortality at 2 yr same as with maximal medical therapy, but better exercise capacity and quality of life with LVRS

Stomach and Duodenum

Peptic Ulcer Disease

GASTRIC ULCERS
• see Gastroenterology, G12

Indications for Surgery
• unresponsive to medical treatment (intractability):
  ▪ always operate if fails to heal completely, even if biopsy negative: could be primary gastric lymphoma or adenocarcinoma
  ▪ dysplasia or carcinoma:
    ▪ always biopsy ulcer for malignancy
  ▪ hemorrhage: 3x greater risk of bleeding compared to duodenal ulcers
  ▪ complications: obstruction, perforation, bleeding
  ▪ surgical treatment is increasingly rare due to H. pylori eradication and medical treatment

Procedures
• distal gastrectomy with ulcer excision: Billroth I or Billroth II (see Figure 9)
• vagotomy and pyloroplasty only if acid hypersecretion (rare)
• wedge resection if possible or biopsy with primary repair

DUODENAL ULCERS
• see Gastroenterology, Bleeding Peptic Ulcer, G13 and Peptic Ulcer Disease, G12
• most within 2 cm of pylorus (duodenal bulb)

Indications for Surgery
• hemorrhage, rebleed in hospital, perforation, gastric outlet obstruction
  ▪ decision to operate based on amount of blood loss (usually >8 units), rate of bleeding and hemodynamic stability
  ▪ intractable despite medical management (endoscopy)
Procedures
- Graham patch of perforated ulcer – plication of ulcer and omental patch
- oversewing of bleeding ulcer ± pyloroplasty
- pyloroplasty, gastroduodenostomy or gastrojejunostomy (improved drainage)
- antrectomy (eliminate hormonal stimulation from the antrum)
- gastric resection (decrease the number of parietal cells)
- vagotomy
  - rarely done now due to H. pylori eradication and proton pump inhibitors

Complications of Surgery
- retained antrum
- fistula (gastrocolic/gastrojejunal)
- dumping syndrome, postvagotomy diarrhea, afferent loop syndrome (see Complications of Gastric Surgery, GS20)

Table 5. Complications of Duodenal Ulceration

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Perforated ulcer (typically on anterior surface)</td>
<td>Sudden onset of pain (possibly in RLQ due to track down right paracolic gutter) Acute abdomen: rigid, diffuse guarding Ileus Initial chemical peritonitis followed by bacterial peritonitis</td>
<td>Investigation: CXR – free air under diaphragm (70% of patients) Treatment: Oversew ulcer (plication) and omental (Graham) patch – most common treatment</td>
</tr>
<tr>
<td>Posterior penetration</td>
<td>Elevated amylase/lipase if penetration into pancreas Constant mid-epigastric pain burrowing into back, unrelated to meals</td>
<td>Resuscitation initially with crystalloids; blood transfusion if necessary Diagnostic and/or therapeutic endoscopy (laser, cautery or injection); if recurs, may have second scope Consider interventional radiology: angiography with embolization/coiling Surgery if severe or recurrent bleeding, hemodynamically unstable, or failure of endoscopy and IR: oversewing of ulcer, pyloroplasty</td>
</tr>
<tr>
<td>Hemorrhage (typically on posterior surface)</td>
<td>Gastroduodenal artery involvement</td>
<td>NG decompression and correction of hypochloremic, hypokalemic metabolic alkalosis Medical management initially: high dose PPI therapy Surgical resection if obstruction does not resolve: either Billroth I, pyloroplasty or gastrojejunostomy</td>
</tr>
<tr>
<td>Gastric outlet obstruction</td>
<td>Ulcer can lead to edema, fibrosis of pyloric channel, neoplasm Nausea and vomiting (undigested food, non-bilious), dilated stomach, crampy abdominal pain Succussion splash (splashing noise heard with stethoscope over the stomach when patient is shaken) Auscultate gas and fluid movement in obstructed organ</td>
<td>NG decompression and correction of hypochloremic, hypokalemic metabolic alkalosis Medical management initially: high dose PPI therapy Surgical resection if obstruction does not resolve: either Billroth I, pyloroplasty or gastrojejunostomy</td>
</tr>
</tbody>
</table>

Gastric Carcinoma

Epidemiology
- male:female = 3:2
- incidence of adenocarcinoma <10 (U.S.) vs. 60 (Japan, Korea) per 100,000 (incidence highest in Asia and Latin America)
- most common age group = 50-59 yr
- incidence has decreased by 2/3 in past 50 yr

Risk Factors
- H. pylori, causing chronic atrophic gastritis
- hereditary nonpolyposis colorectal cancer (HNPPC), hereditary diffuse gastric carcinoma (HDGC)
- smoking, alcohol, smoked food, nitrosamines
- pernicious anemia associated with achlorhydria and chronic atrophic gastritis
- gastric adenomatous polyps
- previous partial gastrectomy (>10 yr post-gastrectomy)
- hypertrophic gastropathy
- blood type A
Clinical Features
- clinical suspicion:
  - ulcer fails to heal
  - lesion on greater curvature of stomach or cardia
- asymptomatic, insidious or late onset of symptoms:
  - postprandial abdominal fullness, vague epigastric pain
  - anorexia, weight loss
  - burping, nausea, vomiting, dyspepsia, dysphagia
  - hepatomegaly, epigastric mass (25%)
  - hematemesis, fecal occult blood, melena, iron-deficiency anemia
- metastasis:
  - peritoneum, liver, lung, brain

Investigations
- OGD and biopsy; EUS to assess preoperative T-stage and N-stage
- chest/abdo/pelvis CT (for metastatic work-up see Table 7)

Treatment
- adenocarcinoma:
  - proximal lesions:
    - total gastrectomy and esophagojejunostomy – Roux-en-Y (see Figure 9)
  - distal lesions:
    - distal gastrectomy: wide margins, en bloc removal of omentum and lymph nodes
    - palliation:
      - gastric resection to decrease bleeding and relieve obstruction, enables the patient to eat
      - radiation therapy
      - studies are showing larger role for chemotherapy
  - lymphoma:
    - H. pylori eradication, chemotherapy ± radiation, surgery in limited cases (perforation, bleeding, obstruction)

Gastrointestinal Stromal Tumour (GIST)

Epidemiology
- most common mesenchymal neoplasm of GI tract
- derived from interstitial cells of Cajal (cells associated with Auerbach’s plexus that have autonomous pacemaker function which coordinate peristalsis throughout the GI tract)
- 75-80% associated with tyrosine kinase (c-KIT) mutations
- most common in stomach (50%) and proximal small intestine (25%), but can occur anywhere along GI tract
- typically present with vague abdominal mass, feeling of abdominal fullness, or with secondary symptoms of bleeding and anemia
- often discovered incidentally on CT, laparotomy or endoscopy

Risk Factors
- Carney’s triad: GISTs, paraganglioma, and pulmonary chondroma
- Type IA neurofibromatosis
Investigations

- pre-operative biopsy: controversial, but useful for indeterminate lesions:
  - not recommended if index of suspicion for GIST is high
  - percutaneous biopsy is NOT recommended due to high friability and risk of peritoneal spread

Treatment

- surgical resection if >2 cm; follow with serial endoscopy if <2 cm and resect if growing or symptomatic
- localized GIST
  - surgical resection with preservation of intact pseudocapsule
  - lymphadenectomy NOT recommended, as GISTs rarely metastasize to lymph nodes
  - consider imatinib postop for high-risk GIST (large, >4 cm with significant mitotic activity)
- advanced disease (i.e. metastases to liver and/or peritoneal cavity)
  - chemotherapy with imatinib

Prognosis

- risk of metastatic potential depends on:
  - tumour size (worse if >10 cm)
  - mitotic activity (worse if >5 mitotic figures or 50/hpf)
  - degree of nuclear pleomorphism
  - location: with identical sizes, extra-gastric location has a higher risk of progression than GISTs in the stomach
- mets to liver, omentum, peritoneum; nodal mets rare

Bariatric Surgery

- weight reduction surgery for morbid obesity
- indications: BMI >40 or BMI >35 with related comorbidity (e.g. DM, CAD, sleep apnea, severe joint disease)
- requires multidisciplinary evaluation and follow-up

Surgical Options

- malabsorptive/restrictive:
  - laparoscopic Roux-en-Y gastric bypass (most common – see Figure 9)
  - staple off small gastric pouch (restrictive) with Roux-en-Y limb to pouch (malabsorptive) with dumping syndrome physiology
  - most effective, higher complication rates
- restrictive:
  - laparoscopic adjustable gastric banding
  - silicone band around fundus creates pouch, adjustable through port under skin
  - laparoscopic vertical banded gastroplasty
  - vertical staple small gastric pouch with placement of silastic ring band
- malabsorptive:
  - biliopancreatic diversion with duodenal switch
  - gastrectomy, enterointerostomy, duodenal division closure and duodenoenterostomy

Complications

- perioperative mortality ~1% (anastomotic leak with peritoneal signs, PE)
- obstruction at enterointerostomy (see Complications of Gastric Surgery, below)
- staple line dehiscence
- dumping syndrome
- cholelithiasis due to rapid weight loss (20-30%)
- band abscess (if long-term)

Complications of Gastric Surgery

- most resolve within 1 yr (see Figure 10)

Alkaline Reflux Gastritis (see Figure 10A)
- duodenal contents (bilious) reflux into stomach causing gastritis ± esophagitis
- treatment:
  - medical: H2-blocker, metoclopramide, cholestyramine (bile acid sequestrant)
  - surgical: conversion of Billroth I or II to Roux-en-Y
Afferent Loop Syndrome (see Figure 10B)
- accumulation of bile and pancreatic secretions causes intermittent mechanical obstruction and distention of afferent limb
- clinical features:
  - early postprandial distention, RUQ pain, nausea, bilious vomiting, anemia
  - treatment: surgery (conversion to Roux-en-Y increases afferent loop drainage)

Dumping Syndrome (see Figure 10C)
- early – 15 min post-prandial:
  - etiology:
    - hyperosmotic chyme released into small bowel (fluid accumulation and jejunal distention)
  - clinical features:
    - post-prandial symptoms
    - epigastric fullness or pain, emesis, nausea, diarrhea, palpitations, dizziness, tachycardia, diaphoresis
  - treatment:
    - small multiple low carbohydrate, low fat and high protein meals and avoidance of liquids with meals
    - last resort is interposition of antiperistaltic jejunal loop between stomach and small bowel to delay gastric emptying
- late – 3 h post-prandial:
  - etiology: large glucose load leads to large insulin release and hypoglycemia
  - treatment: small snack 2 h after meals

Blind-Loop Syndrome (see Figure 10D)
- bacterial overgrowth of colonic Gram-negative bacteria in afferent limb
- clinical features:
  - anemia/weakness, diarrhea, malnutrition, abdominal pain and hypocalcemia
- treatment: broad-spectrum antibiotics, surgery (conversion to Billroth I)

Postvagotomy Diarrhea (see Figure 10E)
- up to 25%
- bile salts in colon inhibit water resorption
- treatment: medical (cholestyramine), surgical (reversed interposition jejunal segment)

Small Intestine

Tumours of Small Intestine

BENIGN TUMOURS
- 10x more common than malignant
- usually asymptomatic until large
- most common sites: terminal ileum, proximal jejunum
- polyps:
  - adenomas
  - hamartomas
  - familial adenomatous polyposis (FAP) (see Familial Colon Cancer Syndromes, GS33)
  - juvenile polyps
- other: leiomyomas, lipomas, hemangiomas

Hernia

**Definition**
- fascial defect → protrusion of a viscus into an area in which it is not normally contained

**Epidemiology**
- M:F = 9:1
- lifetime risk of developing a hernia: males 20-25%, females 2%
- 50% are indirect inguinal hernia, 25% are direct inguinal hernia, 5% are femoral
- most common surgical disease of males

**Risk Factors**
- activities which increase intra-abdominal pressure:
  - obesity, chronic cough, pregnancy, constipation, straining on urination or defecation, ascites, heavy lifting
  - congenital abnormality (e.g. patent processus vaginalis)
  - previous hernia repair

**Clinical Features**
- mass of variable size
- tenderness worse at end of day, relieved with supine position or with reduction
- abdominal fullness, vomiting, constipation
- transmits palpable impulse with coughing or straining

**Investigations**
- physical examination usually sufficient
- ultrasound ± CT (CT required for obturator hernias, internal abdominal hernias and Spigelian femoral hernias in obese patients)
Classification
- complete: hernia sac and contents protrude through defect
- incomplete: partial protrusion through the defect
- internal hernia: sac herniating into or involving intra-abdominal structure
- external hernia: sac protrudes completely through abdominal wall
- strangulated hernia: vascular supply of protruded viscus is compromised (ischemia)
  - requires emergency repair
- incarcerated hernia: irreducible hernia, not necessarily strangulated
- Richter’s hernia: only part of bowel circumference (usually anti-mesenteric border) is incarcerated or strangulated so may not be obstructed
  - a strangulated Richter’s hernia may self-reduce and thus be overlooked, leaving a gangrenous segment at risk of perforation
- sliding hernia: part of wall of hernia formed by protruding viscus (usually cecum)

Anatomical Types
- groin (see Tables 8 and 9)
  - indirect and direct inguinal, femoral (see Figure 13)
  - pantoloan: combined direct and indirect hernias, peritoneum draped over inferior epigastric vessels
- epigastric: defect in linea alba above umbilicus
- incisional: ventral hernia at site of wound closure, may be secondary to wound infection
- other: Littre’s (involving Meckel’s), Amyand’s (containing appendix), lumbar, obturator, parastomal, umbilical, Spigelian (ventral hernia through linea semilunaris)

Complications
- incarceration: irreducible
- strangulation: irreducible with resulting ischemia
  - small, new hernias more likely to strangulate
  - femoral >> indirect inguinal > direct inguinal
- intense pain followed by tenderness
- intestinal obstruction, gangrenous bowel, sepsis
- surgical emergency
- DO NOT attempt to manually reduce hernia if septic or if contents of hernial sac gangrenous
  - will cause closed loop SBO – and EMERGENCY

Treatment
- surgical treatment (herniorrhaphy) is only to prevent strangulation and evisceration, for symptomatic relief, for cosmesis; if asymptomatic can delay surgery
- repair may be done open or laparoscopic and may use mesh for tension-free closure
- most repairs are now done using tension free techniques – a plug in the hernial defect and a patch over it or patch alone
- observation is acceptable for small asymptomatic inguinal hernias

Postoperative Complications
- recurrence (15-20%):
  - risk factors: recurrent hernia, age >50, smoking, BMI ≥25, poor pre-op functional status (ASA ≥3 – see Anesthesia, A3), associated medical conditions: type II DM, hyperlipidemia, immunosuppression, any comorbid conditions increasing intra-abdominal pressure
  - less common with mesh/”tension-free” repair
- scrotal hematoma (3%):
  - painful scrotal swelling from compromised venous return of testes
  - deep bleeding: may enter retroperitoneal space and not be initially apparent
  - difficulty voiding
- nerve entrapment:
  - ilioinguinal (causes numbness of inner thigh or lateral scrotum)
  - genital branch of genitofemoral (in spermatic cord)
- stenosis/occlusion of femoral vein:
  - acute leg swelling
- ischemic colitis

Anatomical Types
- Spermatic Cord
  - vas deferens, testicular artery/veins, genital branch of genitofemoral nerve, lymphatics, cremaster muscle, hernia sac

Inguinal canal walls = MALT x 2
- Roof 2M 2 muscles
- Ant. wall 2A 2 aponesineus
- Floor 2L 2 ligaments
- Post. wall 2T 2 tendons

Cooper’s Ligament, which runs on the pectineal line of the pubic bone, is often exploited in hernia repair.

Contents of Spermatic Cord
- vas deferens, testicular artery/veins, genital branch of genitofemoral nerve, lymphatics, cremaster muscle, hernia sac

Watchful Waiting vs. Repair of Inguinal Hernia in Minimally Symptomatic Men: A Randomized Clinical Trial
JAMA 2008;299:235-239

**Purpose:** To compare pain and the physical component score (PCS) of the Short Form-36 (SF-36) Version 2 survey at 2 yr in men with minimally symptomatic inguinal hernias treated with watchful waiting or surgical repair.

**Methods:** RCT of 720 men (n=364 watchful waiting, n=356 surgical repair) followed up for 2-4.5 yr. Watchful waiting patients were followed up at 6 mo and annually and watched for hernia symptoms; repair patients received standard open tension-free repair and were followed up at 3 and 6 mo and annually. The main outcome was pain and discomfort interfering with usual activities at 2 yr and change in PCS from baseline to 2 yr. Secondary outcomes were complications, patient-reported pain, functional status, activity levels, and satisfaction with care.

**Results:** Primary intention-to-treat outcomes were similar at 2 yr for watchful waiting vs. surgical repair: pain limiting activities (5.1% vs. 2.2%, respectively; P = .18 [convergent]; PCS improvement over baseline, 0.29 points vs. 0.13 points; P = .78). Twenty-three percent of patients assigned to watchful waiting crossed over to receive surgical repair (increase in hernia-related pain was the most common reason offered); 1% assigned to receive repair crossed over to watchful waiting. Self-reported pain in watchful-waiting patients crossing over improved after repair. Occurrence of postoperative hernia-related complications was similar in patients who received repair as assigned and in watchful-waiting patients who crossed over. One watchful-waiting patient (0.3%) experienced acute hernia incarceration without strangulation within 2 yr; a second had acute incarceration with bowel obstruction at 4 yr, with a frequency of 1.8/100 patient/yr inclusive of patients followed up for as long as 4.5 yr.

**Conclusion:**Watchful waiting is an acceptable option for men with minimally symptomatic inguinal hernias. Delaying surgical repair until symptoms increase is safe because acute hernia incarcerations occur rarely.

#### Bowel Obstruction

**Definition**
- partial or complete blockage of the bowel resulting in failure of intestinal contents to pass through lumen

**Pathogenesis**
- disruption of the normal flow of intestinal contents $\rightarrow$ proximal dilatation + distal decompression
- may take 12-24 h to decompress, therefore passage of feces and flatus may occur after the onset of obstruction
- bowel ischemia may occur if blood supply is strangulated or bowel wall inflammation leads to venous congestion
- bowel wall edema and disruption of normal bowel absorptive function $\rightarrow$ increased intraluminal fluid $\rightarrow$ transudative fluid loss into peritoneal cavity, electrolyte disturbances

**Differential Diagnosis**
- small bowel obstruction (SBO), large bowel obstruction (LBO), pseudo-obstruction

**Clinical Features**
- must differentiate between obstruction and ileus, and characterize obstruction as acute vs. chronic, partial vs. complete (constipation vs. obstipation), small vs. large bowel, strangulating vs. non-strangulating, and with vs. without perforation

</tbody>
</table>
Complications (of total obstruction)
• strangulating obstruction (10% of bowel obstructions) = surgical emergency:
  ▪ cramping pain turns to continuous ache, hematemesis, melena (if infarction)
  ▪ fever, leukocytosis, tachycardia
  ▪ peritoneal signs, early shock
  ▪ see Intestinal Ischemia, GS28
• other:
  ▪ perforation: secondary to ischemia and luminal distention
  ▪ septicemia
  ▪ hypovolemia (due to third spacing)

Investigations
• radiological:
  ▪ upright CXR or left lateral decubitus (LLD) to rule out free air, usually seen under the right hemidiaphragm
  ▪ abdominal x-ray (3 views) to determine SBO vs. LBO vs. ileus (see Table 10)
  ▪ if ischemic bowel look for: free air, pneumatosis, thickened bowel wall, air in portal vein, dilated small and large bowels, thickened or hose-like haustra (normally finger-like projections)
• other:
  ▪ most used: CT provides information on level of obstruction, severity, cause
    – important to r/o closed loop obstruction, especially in the elderly
  ▪ less used: upper GI series/small bowel series for SBO (if no cause apparent, i.e. no hernias, no previous surgeries)
  ▪ if suspect LBO, consider a rectal water-soluble (Gastrografin® for PO/PR; Hypaque® for IV) enema rather than barium enema (can thicken and cause complete obstruction)
  ▪ may consider ultrasound or MRI in pregnant patients
• laboratory:
  ▪ may be normal early in disease course
  ▪ BUN, creatinine, hematocrit (hemoconcentration) to assess degree of dehydration
  ▪ fluid, electrolyte abnormalities
  ▪ amylase elevated
  ▪ metabolic alkalosis due to frequent emesis
  ▪ if strangulation: leukocytosis with left shift, lactic acidosis, elevated LDH (late signs)

Treatment
• stabilize vitals, fluid and electrolyte resuscitation (with normal saline/Ringer’s first, then with added potassium after fluid deficits are corrected)
• NG tube to relieve vomiting, prevent aspiration and decompress small bowel by prevention of further distention by swallowed air
• Foley catheter to monitor in/outs

Small Bowel Obstruction (SBO)

<td></td>
<td></td>
</tr>
</tbody>
</table>

Treatment
• consider whether complete or partial obstruction, ongoing or impending strangulation, location and cause:
  ▪ SBO with history of abdo/pelvic surgery → conservative management (likely to resolve) → surgery if no resolution in 48-72 h or complications
  ▪ complete SBO, strangulation → urgent surgery after stabilizing patient with fluid resuscitation
  ▪ SBO with no previous surgery and no evidence of carcinomatosis → operate
  ▪ trial of medical management may be indicated in Crohn’s, recurrent SBO, carcinomatosis
  ▪ NGT decompression, GI rest, serial abdominal exams
  ▪ special case: early postoperative SBO (within 30 d of abdominal surgery) – prolonged trial of conservative therapy may be appropriate, surgery is reserved for complications such as strangulation

Prognosis
• mortality: non-strangulating <1%, strangulating 8% (25% if >36 h), ischemic = up to 50%
Large Bowel Obstruction (LBO)

Etiology

Table 12. Common Causes of LBO

Clinical Features (unique to LBO)

• open loop (10-20%) (safer):
  - incompetent ileocecal valve allows relief of colonic pressure as contents reflux into ileum, therefore clinical presentation similar to SBO

• closed loop (80-90%) (dangerous):
  - competent ileocecal valve, resulting in proximal and distal occlusions
  - massive colonic distention → increased pressure in cecum → bowel wall ischemia → necrosis → perforation

Treatment

• surgical correction of obstruction (usually requires resection + temporary diverting colostomy)
• volvulus requires sigmoidoscopic or endoscopic decompression followed by operative reduction if unsuccessful
  - if successful, consider sigmoid resection on same admission
• cecal volvulus can be a true volvulus or a cecal ‘bascul’ – both need surgical treatment

Prognosis

• overall mortality: 10%
• cecal perforation + feculent peritonitis: 20% mortality

Colonic Pseudo-Obstruction

• aka paralytic ileus of large bowel

Definition

• condition with symptoms of intestinal blockage without any physical signs of blockage

Differential Diagnosis

• acute: toxic megacolon, trauma, postoperative (especially post orthopedic procedures with prolonged immobilization), neurologic disease, retroperitoneal disease, medications (narcotics, psychiatric)
• chronic: neurologic disease (enteric, central, peripheral nervous system), scleroderma

Toxic Megacolon

Pathogenesis

• extension of inflammation into smooth muscle layer causing paralysis
• damage to myenteric plexus and electrolyte abnormalities are not consistently found

Etiology

• inflammatory bowel disease (ulcerative colitis > Crohn’s disease)
• infectious colitis: bacterial (C. difficile, Salmonella, Shigella, Campylobacter), viral (cytomegalovirus), parasitic (E. histolytica)
• volvulus, diverticulitis, ischemic colitis, obstructing colon cancer are rare causes

Clinical Features

• infectious colitis usually present for >1 wk before colonic dilatation
• improvement of diarrhea may portend onset of megacolon
• abdominal distention, tenderness, ± local/general peritoneal signs (suggest perforation)
• triggers: hypokalemia, constipating agents (opioids, antidepressants, loperamide, anticholinergics), barium enema, colonoscopy

In a patient with clinical LBO consider impending perforation when:
- Cecum ≥12 cm in diameter
- Tenderness present over cecum

Colon is MEGA and patient is TOXIC.
Diagnostic Criteria
• must have both colitis and systemic manifestations for diagnosis
• radiologic evidence of dilated colon
• three of: fever, HR >120, WBC >10.5, anemia
• one of: fluid and electrolyte disturbances, hypotension, altered LOC

Investigations
• CBC (leukocytosis with left shift, anemia from bloody diarrhea), electrolytes, elevated CRP, ESR
• metabolic alkalosis (volume contraction and hypokalemia) and hypoalbuminemia are late findings
• AXR: dilated colon >6 cm (right > transverse > left), loss of haustra
• CT: useful to assess underlying disease

Treatment
• NPO, NG tube, stop constipating agents, correct fluid and electrolyte abnormalities, transfusion
• serial AXRs
• broad-spectrum antibiotics (reduce sepsis, anticipate perforation)
• aggressive treatment of underlying disease (e.g. steroids in IBD, metronidazole for C. difficile)
• indications for surgery (50% improve on medical management):
  ▪ worsening or persisting toxicity or dilation after 48-72 h
  ▪ severe hemorrhage, perforation
  ▪ high lactate and WBC especially for C. difficile
• procedure: subtotal colectomy + end ileostomy (may be temporary, with second operation for re-anastomosis later)

Prognosis
• average 25-30% mortality

Paralytic Ileus

Pathogenesis
• temporary paralysis of the myenteric plexus

Associations
• postoperative, intra-abdominal sepsis, medications (opiates, anesthetics, psychotropics), electrolyte disturbances (Na⁺, K⁺, Ca²⁺), C. difficile, inactivity

Treatment
• NG decompression, NPO, fluid resuscitation, correct causative abnormalities (e.g. sepsis, medications, electrolytes), consider TPN for prolonged ileus
• post-op: gastric and small bowel motility returns by 24-48 h, colonic motility by 3-5 d
• current interest in novel therapies such as gum chewing and pharmacologic therapy (opioid antagonists)

Ogilvie’s Syndrome

• acute pseudo-obstruction
• distention of colon without mechanical obstruction in distal colon
• arises in bedridden patients with serious extraintestinal illness or trauma
• exact mechanism unknown, likely autonomic motor dysregulation → possibly sympathetic deprivation to colon, unopposed parasympathetic tone, and interruption of sacral parasympathetic tone to distal bowel
• first presents with abdominal distention (>90%) ± tenderness
• later symptoms mimic true obstruction

Associations
• most common: trauma, infection, cardiac (MI, CHF)
• disability (long term debilitation, chronic disease, bed-bound nursing home patients, paraplegia), drugs (narcotic use, laxative abuse, polypharmacy), other (recent orthopedic or neurosurgery, post-partum, electrolyte abnormalities including hypokalemia, retroperitoneal hematoma, diffuse carcinomatosis)

Investigations
• AXR: cecal dilatation – if diameter ≥12 cm, increased risk of perforation

Treatment
• treat underlying cause
• NPO, NG tube
• decompression: rectal tube, colonoscopy, neostigmine (cholinergic drug), surgical decompression (ostomy/resection) uncommon
• surgery (extremely rare): if perforation, ischemia or failure of conservative management

Prognosis
• most resolve with conservative management
Intestinal Ischemia

Etiology
• acute:
  ▪ arterio-occlusive mesenteric ischemia (AOMI)
  ▪ thrombotic, embolic, extrinsic compression (e.g. strangulating hernia)
  ▪ non-occlusive mesenteric ischemia (NOMI)
  ▪ mesenteric vasoconstriction secondary to systemic hypoperfusion (preserves supply to vital organs)
  ▪ mesenteric venous thrombosis (MVT)
  ▪ consider hypercoagulable state (i.e. rule out malignancy), DVT (prevents venous outflow)
• chronic: usually due to atherosclerotic disease – look for CVD risk factors

Clinical Features
• acute: severe abdominal pain out of proportion to physical findings, vomiting, bloody diarrhea, bloating, minimal peritoneal signs early in course, hypotension, shock, sepsis
• chronic: postprandial pain, fear of eating, weight loss
• common sites: superior mesenteric artery (SMA) supplied territory, “watershed” areas of colon – splenic flexure, left colon, sigmoid colon

Investigations
• laboratory: leukocytosis (non-specific), lactic acidosis (late finding)
  ▪ amylase, LDH, CK, ALP can be used to observe progress
  ▪ hypercoagulability workup if suspect venous thrombosis
• AXR: portal venous gas, intestinal dilatation, SMA or SMV thrombus, mesenteric/portal venous gas, pneumatosis
• CT angiography is the gold standard for acute arterial ischemia

Treatment
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis

• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• fluid resuscitation, correct metabolic acidosis, NPO, NG decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
• angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, exploratory laparotomy
• prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis

Appendix

Appendicitis

Epidemiology
• 6% of population, M>F
• 80% between 5-35 yr of age

Pathogenesis
• luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess (walled off by omentum) or peritonitis
• etiology:
  ▪ children or young adult: hyperplasia of lymphoid follicles, initiated by infection
  ▪ adult: fibrosis/stricture, fecolith, obstructing neoplasm
  ▪ other causes: parasites, foreign body

Clinical Features
• most reliable feature is progression of signs and symptoms
• low grade fever (38°C), rises if perforation
• abdominal pain then anorexia, nausea and vomiting
• classic pattern: pain initially periumbilical; constant, dull, poorly localized, then well localized pain over McBurney’s point
• due to progression of disease from visceral irritation (causing referred pain from structures of the embryonic midgut, including the appendix) to irritation of parietal structures
• McBurney’s sign

Modified Alvarado Score for Acute Appendicitis
• 1 point per:
  ▪ Migratory right iliac fossa pain (1 point)
  ▪ Anorexia (1 point)
  ▪ Nausea/vomiting (1 point)
  ▪ Tenderness in right iliac fossa (2 points)
  ▪ Fever >37.5°C (1 point)
  ▪ Leukocytosis (2 points)
• 0-3 = low risk, discharge to return if no improvement
• 4-6 = moderate risk, admit, observe, repeat examinations
• Male 7-9 = appendectomy
• Female (not pregnant) 7-9 = diagnostic laparoscopy ± appendectomy

Laparoscopic vs. Open Appendectomy
• Wound infection less likely
• Intra-abdominal abscesses 2 times more likely
• Reduced pain on POD #1
• Reduced hospital stay by 1.1 d
• Sooner return to normal activity, work and sport
• Costs outside hospital are reduced

Laparoscopic Surgery
• Wound infection less likely
• Intra-abdominal abscesses 2 times more likely
• Reduced pain on POD #1
• Reduced hospital stay by 1.1 d
• Sooner return to normal activity, work and sport
• Costs outside hospital are reduced

Open Surgery
• Shorter duration of surgery
• Lower operation costs

Cochrane DB Syst Rev 2010;10:CD001546

Figure 14. Appendix anatomy
• signs:
  ▪ inferior appendix: McBurney’s sign (see GS28), Rovsing’s sign (palpation pressure to left abdomen causes McBurney’s point tenderness)
  ▪ retrocecal appendix: psoas sign (pain on flexion of hip against resistance or passive hyperelevation of hip)
  ▪ pelvic appendix: obturator sign (flexion then external or internal rotation about right hip causes pain)
• complications:
  ▪ perforation (especially if >24 h duration)
  ▪ abscess, phlegmon

Investigations
• laboratory:
  ▪ mild leukocytosis with left shift (may have normal WBC counts)
  ▪ higher leukocyte count with perforation
  ▪ β-hCG to rule out ectopic pregnancy
  ▪ urinalysis
• imaging:
  ▪ upright CXR, AXR: usually nonspecific – free air if perforated (rarely), calcified fecolith, loss of psoas shadow, RLQ ileus
  ▪ ultrasound: may visualize appendix, but also helps rule out gynecological causes – overall accuracy 90-94%, can rule in but CANNOT rule out appendicitis (if >6 mm, SENS/SPEC/NPV/PPV 98%)
  ▪ CT scan: thick wall, appendicolith, inflammatory changes – overall accuracy 94-100%, optimal investigation

Treatment
• hydrate, correct electrolyte abnormalities
• surgery (gold standard, 20% mortality with perforation especially in elderly) + antibiotic coverage
  ▪ if localized abscess (palpable mass or large phlegmon on imaging and often pain >4-5 d), consider radiologic drainage + antibiotics x 14 d ± interval appendectomy in 6 wk (controversial)
  ▪ appendectomy:
    ▪ laparoscopic vs. open (see sidebar)
    ▪ complications: spillage of bowel contents, pelvic abscess, enterocutaneous fistula
    ▪ perioperative antibiotics:
      ▪ cefazolin + metronidazole (no post-op antibiotic unless perforated)
      ▪ other choices: 2nd/3rd generation cephalosporin for aerobic gut organisms
    ▪ colonoscopy in the elderly to rule out other etiology (neoplasm)
• prophylactic antibiotics against postoperative infections after appendectomy.
  ▪ Various prophylactic antibiotic regimens are effective in preventing postoperative infection and abscess rates.
  ▪ Treatment with antibiotics decreased wound infection, intra abdominal abscess, length of hospital stay, and mortality.
  ▪ The main outcomes of interest were patients undergoing appendectomy for suspected appendicitis. The main outcomes of interest were wound infection, intra abdominal abscess, length of hospital stay, and mortality.
  ▪ Results: 45 studies (n = 9576) were included.
  ▪ Conclusion: Various prophylactic antibiotic regimens are effective in preventing postoperative complications after appendectomy.

Prognosis
• mortality rate: 0.08% (non-perforated), 0.5% (perforated appendicitis)

Tumours of the Appendix
CARCINOID TUMOURS (most common type)
• see Tumours of Small Intestines: Carcinoid section, GS21

ADENOCARCINOMA
• 50% present as acute appendicitis
• spreads rapidly to lymph nodes, ovaries, and peritoneal surfaces
• treatment: right hemicolectomy

OTHER
• malignant mucinous cystadenocarcinoma

Inflammatory Bowel Disease (IBD)
• see Gastroenterology, G19

Principles of Surgical Management
• can alleviate symptoms, address complications, improve quality of life
• conserve bowel: resect as little as possible to avoid short gut syndrome
• perioperative management:
  ▪ optimize medical status: may require TPN (especially if >7 d NPO) and bowel rest
  ▪ hold immunosuppressive therapy pre-op, provide pre-op stress dose of corticosteroid if patient had recent steroid therapy, taper steroids post-op
  ▪ DVT prophylaxis: heparin (IBD patients at increased risk of thromboembolic events)
Crohn’s Disease

- see Gastroenterology, G20

Treatment
- surgery is NOT curative, but over lifetime ~70% of Crohn's patients will have surgery
- indications for surgical management:
  - failure of medical management
  - SBO (due to stricturing/inflammation): indication in 50% of surgical cases
  - abscess, fistula (enterocolic, vesicular, vaginal, cutaneous abscess), quality of life, perforation, hemorrhage, chronic disability, failure to thrive (children), perianal disease
- surgical procedures:
  - resection and anastomosis/stoma if active or subacute inflammation, perforation, fistula
  - resection margin only has to be free of gross disease (microscopic disease irrelevant to prognosis)
  - stricturoplasty – widens lumen in chronically scarred bowel: relieves obstruction without resecting bowel (contraindicated in acute inflammation)

Complications of Treatment
- short gut syndrome (diarrhea, steatorrhea, malnutrition)
- fistulas
- gallstones (if terminal ileum resected, decreased bile salt resorption → increased cholesterol precipitation)
- kidney stones (loss of calcium in diarrhea → increased oxalate absorption and hyperoxaluria → stones)

Prognosis
- recurrence rate at 10 yr: ileocolic (25-50%), small bowel (50%), colonic (40-50%)
- re-operation at 5 yr: primary resection (20%), bypass (50%), stricturoplasty (10% at 1 yr)
- 80-85% of patients who need surgery lead normal lives
- mortality: 15% at 30 yr

Ulcerative Colitis

- see Gastroenterology, G22

Treatment
- indications for surgical management:
  - failure of medical management (including inability to taper steroids)
  - complications: hemorrhage, obstruction, perforation, toxic megacolon (emergency), failure to thrive (children)
  - reduce cancer risk (1-2% risk per year after 10 yr of disease)
- surgical procedures:
  - proctocolectomy and ileal pouch-anal anastomosis (IPAA) ± rectal mucosectomy (operation of choice)
  - proctocolectomy with permanent end ileostomy (if not a candidate for ileoanal procedures)
  - colectomy and IPAA ± rectal mucosectomy
  - in emergency: total colectomy and ileostomy with Hartmann closure of the rectum, rectal preservation

Complications of Treatment
- early: bowel obstruction, transient urinary dysfunction, dehydration (high stoma output), anastomotic leak
- late: stricture, anal fistula/abscess, pouchitis, poor anorectal function, reduced fertility

Prognosis
- mortality: 5% over 10 yr
- total proctocolectomy will completely eliminate risk of cancer
- perforation of the colon is the leading cause of death from ulcerative colitis
Diverticular Disease

Definitions
- diverticulum: abnormal sac-like protrusion from the wall of a hollow organ
- diverticulosis: presence of multiple diverticula
- diverticulitis: inflammation of diverticula
- true (congenital) diverticuli: contain all layers of colonic wall, often right-sided
- false (acquired) diverticuli: contain mucosa and submucosa, often left-sided

Diverticulosis

Epidemiology
- 5-50% of Western population, lower incidence in non-Western countries, M=F
- prevalence is age dependent: <5% by age 40, 30% by age 60, 65% by age 85
- 95% involve sigmoid colon (site of highest pressure)

Pathogenesis
- risk factors:
  - lifestyle: low-fibre diet (predispose to motility abnormalities and higher intraluminal pressure) inactivity, obesity
  - muscle wall weakness from aging and illness (e.g. Ehler-Danlos, Marfan’s)
  - high intraluminal pressures cause outpouching to occur at point of greatest weakness, most commonly where vasa recta penetrate the circular muscle layer, therefore increased risk of hemorrhage

Clinical Features
- uncomplicated diverticulosis: asymptomatic (70-80%)
- episodic abdominal pain (often LLQ), bloating, flatulence, constipation, diarrhea
- absence of fever/leukocytosis
- no physical exam findings or poorly localized LLQ tenderness
- complications:
  - diverticulitis (15-25%): 25% of which are complicated (i.e. abscess, obstruction, perforation, fistula)
  - bleeding (5-15%): PAINLESS rectal bleeding, 30-50% of massive lower GI bleeds
  - diverticular colitis (rare): diarrhea, hematochezia, tenesmus, abdominal pain

Treatment
- uncomplicated diverticulosis: high fibre, education
- diverticular bleed:
  - initially work up and treat as any lower GI bleed
  - if hemorrhage does not stop, resect involved region

Diverticulitis

Epidemiology
- 95% left-sided in patients of Western countries, 75% right-sided in Asian populations

Pathogenesis
- erosion of the wall by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro or macroscopic perforation
- usually mild inflammation with perforation walled off by pericolic fat and mesentery; abscess, fistula or obstruction can ensue
- poor containment results in free perforation and peritonitis
Clinical Features
- depend on severity of inflammation and whether or not complications are present; hence ranges from asymptomatic to generalized peritonitis
- LLQ pain/tenderness (2/3 of patients) often for several days before admission
- constipation, diarrhea, nausea, vomiting, urinary symptoms (with adjacent inflammation)
- complications (25% of cases):
  - abscess: palpable tender abdominal mass
  - fistula: colovesical (most common), coloenteric, colovaginal, colocutaneous
  - colonic obstruction: due to scarring from repeated inflammation
  - perforation: generalized peritonitis (feculent vs. purulent)
    - recurrent attacks rarely lead to peritonitis
- low-grade fever, mild leukocytosis common,
- occult or gross blood in stool rarely coexist with acute diverticulitis

Investigations
- AXR, upright CXR:
  - localized diverticulitis (ileus, thickened wall, SBO, partial colonic obstruction)
  - free air may be seen in 30% with perforation and generalized peritonitis
- CT scan (test of choice): very useful for assessment of severity and prognosis
  - 97% sensitive, 99% specific
  - increased soft tissue density within pericolonic fat secondary to inflammation, diverticula secondary to inflammation, bowel wall thickening, soft tissue mass (pericolic fluid, abscesses), fistula
  - 10% of diverticulitis cannot be distinguished from carcinoma
- Hypaque® (water soluble) enema – safe (under low pressure):
  - saw-tooth pattern (colonic spasm)
  - may show site of perforation, abscess cavities or sinus tracts, fistulas
- elective evaluations: establish extent of disease and rule out other diagnoses (polyps, malignancy) after resolution of acute episode
  - colonoscopy or barium enema and flexible sigmoidoscopy

Treatment
- uncomplicated: conservative management
- outpatient: clear fluids only until improvement and antibiotics (e.g. ciprofloxacin and metronidazole) 7-10 d to cover gram negative rods and anaerobes (e.g. B. fragilis)
- hospitalize: if severe presentation, inability to tolerate oral intake, significant comorbidities, fail to improve outpatient management
- treat with NPO, IVF, IV antibiotics (e.g. IV ceftriaxone + metronidazole, ampicillin, gentamicin)
- indications for surgery:
  - unstable patient with peritonitis
  - Hinchey stage 3-4 (see Table 13)
  - after 1 attack if: (a) immunosuppressed, (b) abscess needing percutaneous drainage
  - consider after 2 or more attacks, recent trend is toward conservative management of recurrent mild/moderate attacks
  - complications: generalized peritonitis, free air, abscess, fistula, obstruction, hemorrhage, inability to rule out colon cancer on endoscopy, or failure of medical management
- surgical procedures:
  - for emergency or complex cases: Hartmann procedure: colon resection + colostomy and rectal stump → colostomy reversal in 3-6 mo (see Figure 16)
  - elective cases or minimal contamination of the abdominal cavity: consider colon resection + primary anastomosis

Prognosis
- mortality rates: 6% for purulent peritonitis, 35% for fecal peritonitis
- recurrence rates: 13-30% after first attack, 30-50% after second attack

**Colorectal Neoplasms**

**Colorectal Polyps**

**Definition**
- polyp: protuberance into the lumen of normally flat colonic mucosa
- sessile (flat) or pedunculated (on a stalk) (see Figure 17)

**Epidemiology**
- 30% of the population have polyps by age 50, 40% by age 60, 50% by age 70

**Clinical Features**
- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, do not typically bleed, tenesmus, intestinal obstruction, mucus
- usually detected during routine endoscopy or familial/high risk screening

**Pathology**
- non-neoplastic:
  - hyperplastic: most common non-neoplastic polyp
  - mucosal polyps: small <5 mm, no clinical significance
  - inflammatory pseudopolyps: associated with IBD, no malignant potential
  - submucosal polyps: lymphoid aggregates, lipomas, leiomyomas, carcinoids
- neoplastic:
  - hamartomas: juvenile polyps (large bowel), Peutz-Jegher syndrome (small bowel)
  - low malignant potential: most spontaneously regress or autoamputate
  - adenomas: premalignant, often carcinoma in situ:
    - some may contain invasive carcinoma (“malignant polyp” – 3-9%): invasion into muscularis
    - malignant potential: villous > tubulovillous > tubular (see Table 14)

**Table 14. Characteristics of Tubular vs. Villous Polyps**

**Investigations**
- colonoscopy is the gold standard for diagnosis and treatment of colonic polyps
- CT colonography: increasing in availability; patients still require bowel prep and will require colonoscopy if polyps are identified
- other: flexible sigmoidoscope if polyps are detected, proceed to colonoscopy for examination of entire bowel and biopsy

**Treatment**
- indications: symptoms, malignancy or risk of malignancy (i.e. adenomatous polyps)
- endoscopic removal of entire growth
- surgical resection for those invading into muscularis (high risk of malignancy) and those too large to remove endoscopically
- follow-up endoscopy 1 yr later, then every 3-5 yr

**Familial Colon Cancer Syndromes**

**FAMILIAL ADENOMATOUS POLYPOSIS (FAP)**

**Pathogenesis**
- autosomal dominant (AD) inheritance, mutation in adenomatous polyposis coli (APC) gene on chromosome 5q21

**Clinical Features**
- hundreds to thousands of colorectal adenomas usually by age 20 (by 40s in attenuated FAP)
- extracolonic manifestations:
  - carcinoma of small bowel (i.e. polyps in colon), bile duct, pancreas, stomach, thyroid, adrenal, small bowel
  - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients; 97% sensitivity
  - virtually 100% lifetime risk of colon cancer (because of number of polyps)
variants:
- Gardner’s syndrome: FAP + extraintestinal lesions (sebaceous cysts, osteomas, desmoid tumours)
- Turcot syndrome: FAP + CNS tumours (childhood cerebellar medulloblastoma)

Investigations
- genetic testing (80-95% sensitive, 99-100% specific) (see sidebar)
- if no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then routine screening
- if polyposis or APC gene mutation found: annual colonoscopy and consider surgery (see Figure 16); consider upper endoscopy to evaluate for periampullary tumours

Treatment
- surgery indicated by age 17-20
- total proctocolectomy with ileostomy or total colectomy with ileorectal anastomosis
- doxorubicin-based chemotherapy
- NSAIDs for intra-abdominal desmoids

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER (HNPCC) – LYNCH SYNDROME

Pathogenesis
- AD inheritance, mutation in a DNA mismatch repair gene (MSH2, MSH6, MLH1) resulting in microsatellite genomic instability and subsequent mutations
- microsatellite instability account for approximately 15% of all colorectal cancers

Clinical Features
- early age of onset, right > left colon, synchronous and metachronous lesions
- mean age of cancer presentation is 44 yr, lifetime risk 70-80% (M>F)
- HNPCC I: hereditary site-specific colon cancer
- HNPCC II: cancer family syndrome – high rates of extracolonic tumours (endometrial, ovarian, hepatobiliary, small bowel)

Diagnosis
- Amsterdam Criteria:
  - 3 or more relatives with verified Lynch syndrome associated cancers, and 1 must be 1st degree relative of the other 2
  - 2 or more generations involved
  - 1 case must be diagnosed before 50 yr old
  - FAP is excluded
- genetic testing (80% sensitive) – colonoscopy mandatory even if negative
  - refer for genetic screening individuals who fulfill EITHER the Amsterdam Criteria (as above) OR the revised Bethesda Criteria (see sidebar)
- colonoscopy (starting age 20) annually
- surveillance for extracolonic lesions

Treatment
- total colectomy and ileorectal anastomosis with annual proctoscopy

Colorectal Carcinoma (CRC)

Epidemiology
- 4th most common cancer (after lung, prostate and breast), 2nd most common cause of cancer death

Risk Factors
- most patients have no specific risk factors
- age >50 (dominant risk factor in sporadic cases), mean age is 70
- genetic: FAP, HNPCC, family history of CRC
- colonic conditions:
  - adenomatous polyps (especially if >1 cm, villous, multiple)
  - IBD (especially UC: risk is 1-2%/yr if UC >10 yr)
  - previous colorectal cancer (also gonadal or breast)
- diet (increased fat, red meat, decreased fibre) and smoking
- diabetes mellitus and acromegaly (insulin and IGF-1 are growth factors for colonic mucosal cells)

Pathogenesis
- adenoma-carcinoma sequence; rarely arise de novo

Staging for CRC
<table>

</table>
Clinical Features (see Table 15)
- often asymptomatic
- haemachorea/melena, abdominal pain, change in bowel habits
- others: weakness, anemia, weight loss, palpable mass, obstruction
- 20% patients have distant metastatic disease at time of presentation
- spread:
  - direct extension, lymphatic, hematogenous (liver most common, lung, bone, brain; tumour of distal rectum → IVC → lungs)
  - peritoneal seeding: ovari, Blumer’s shelf (pelvic cul-de-sac)

</tbody>
</table>

Investigations
- colonoscopy (best), look for synchronous lesions (3-5% of patients); alternative: air contrast barium enema (“apple core” lesion) + sigmoidoscopy
- if a patient is FOBT +ve, or has microcytic anemia or has a change in bowel habits, do colonoscopy
- laboratory: CBC, urinalysis, liver enzymes, liver function test, carcinoembryonic antigen (CEA) (preoperative for baseline, >5 ng/mL have worse prognosis)

Pathology
- staging (see Table 16 and sidebar): chest, abdominal and pelvis CT; bone scan, CT head only if lesions suspected
- rectal cancer: pelvic MRI or endorectal ultrasound to determine T and N stage

Pathology
- signs
- weight loss, weakness, rarely
- exophytic lesions with occult bleeding
- annular, invasive lesions
- ulcerating
- pathologic
- 25% 35% 30%
- frequency
- T4
- T3
- T1
- T0
- primary tumour (T)
- regional lymph nodes (N)
- distant metastasis (M)

Treatment
- colon cancer
  - wide surgical resection of lesion and regional lymphatic drainage; usually colectomy with primary anastomosis
  - curative: wide resection of lesion (5 cm margins) with nodes and mesentery
  - palliative: if distant spread, local control for hemorrhage or obstruction
  - care is taken to not spread tumour by unnecessary palpation
  - cancer-bearing portion of colon is removed according to vascular distribution of segment
  - adjuvant chemotherapy (5-FU or oral capecitabine with oxaliplatin) can be considered for stage II or III

- rectal cancer
  - choice of operation depends on individual case. Types of operations (see Figure 18):
    - low anterior resection of rectum (LAR): curative procedure of choice if adequate distal margins; uses technique of total mesorectal excision
    - abdominoperineal resection of rectum (APR): if adequate distal margins cannot be obtained; involves the removal of distal sigmoid colon, rectum, and anus – permanent end colostomy required
    - local excision: for select T1 lesions only
    - palliative procedures: electrocoagulation or laser photocoagulation for unresectable cancers for symptom relief
    - adjuvant therapy:
      - combined neoadjuvant chemoradiation therapy followed by postoperative adjuvant chemotherapy for stage II and III

Follow-Up
- currently there are no data suggesting optimal follow-up
- combination of periodic CT chest/abdo/pelvis, CEA and colonoscopy is recommended
- CEA to monitor for initial response to treatment, and to assess for recurrence q3mo (not a screening test)
- intensive follow-up improves overall survival in low risk patients

**Angiodysplasia**

**Definition**
- vascular anomaly: focal submucosal venous dilatation and tortuosity

**Clinical Features**
- most frequently in right colon of patients >60 yr old
- bleeding typically intermittent, rarely massive, not usually hypotensive (melena, anemia, guaiac positive stools)

**Investigations**
- colonoscopy: cherry red spots, branching pattern from central vessel
- angiography: early-filling vein, vascular tuft, delayed emptying vein; rarely active bleeding
- RBC technetium-99 scan
- barium enema is contraindicated (obscures other x-rays, i.e. angiogram)

**Treatment**
- none if asymptomatic
cautery, right hemicolectomy, embolization, vasopressin infusion, sclerotherapy, band ligation, laser, octreotide, and rarely segmental resection if other treatments fail

**Volvulus**

**Definition**
- rotation of segment of bowel about its mesenteric axis
- sigmoid (65%), cecum (30%), transverse colon (3%), splenic flexure (2%)
- 5-10% of large bowel obstruction; 25% of intestinal obstruction during pregnancy

**Risk Factors**
- age (50% of patients >70 yr: stretching/elongation of bowel with age is a predisposing factor)
- high fibre diet (can cause elongated/redundant colon), chronic constipation, laxative abuse, pregnancy, bedridden, institutionalization (less frequent evacuation of bowels)
- congenital hypermobile cecum

**Clinical Features**
- symptoms due to bowel obstruction (see GS24) or intestinal ischemia (see GS28)
colic abdominal pain, persistence of pain between spasms, abdominal distention, vomiting

**Investigations**
- AXR (classic findings): "omega", "bent inner-tube", "coffee-bean" signs
- barium/Gastrografin® enema: "ace of spades" (or "bird's beak") appearance due to funnel-like luminal tapering of lower segment towards volvulus
- sigmoidoscopy or colonoscopy as appropriate
- CT

**Treatment**
- initial supportive management(same as initial management for bowel obstruction (see GS24)
cecum:
  - nonsurgical:
    - may attempt colonoscopic detorsion and decompression
  - surgical:
    - right colectomy + ileotransverse colonic anastomosis
sigmoid:
  - nonsurgical:
    - decompression by flexible sigmoidoscopy and insertion of rectal tube past obstruction
    - subsequent elective surgery recommended (50-70% recurrence)
  - surgical: Hartmann procedure (if urgent)
    - indications: strangulation, perforation or unsuccessful endoscopic decompression
Fistula

Definition
- abnormal communication between two epithelialized surfaces (e.g. enterocutaneous, colovesical, aortoenteric, entero-enteric)

Etiology
- foreign object erosion (e.g. gallstone, graft)
- inflammatory states (e.g. infection, IBD (especially Crohn’s), diverticular disease)
- iatrogenic/surgery (e.g. postoperative anastomotic leak, radiation)
- congenital, trauma
- neoplastic

Investigations
- ultrasound, CT scan, fistulogram
- measure amount of drainage from fistula

Treatment
- decrease secretion: octreotide/somatostatin/omeprazole
- surgical intervention: dependent upon etiology (for non-closing fistulas); uncertainty of diagnosis

Stomas

Definition
- an opening of the GI tract onto the surface of the abdomen wall

Ileostomy
- usually positioned in RLQ; ileum is brought through rectus abdominus muscles
- indications: after proctocolectomy for ulcerative colitis, in some cases of Crohn’s disease or familial polyposis
- conventional ileostomy: discharges small quantities of liquid material continuously, appliance (plastic bag attached to a sheet of protective material) required at all times
- continent ileostomy: reservoir is constructed from distal ileum, emptied by inserting catheter into stoma several times a day; rarely used, has mostly been replaced by ileal pouch anal anastomosis

Colostomy
- indications: to decompress an obstructed colon, to protect a distal anastomosis after resection, or to evacuate stool after distal colon or rectum is removed
- colostomies can be done by making an opening in a loop of colon (loop colostomy) or by dividing the colon and bringing out one end (end colostomy)
- most common permanent colostomy is a sigmoid colostomy – expels stool once per day, no appliance required
- chronic paracolostomy hernia is a common complication

Complications (10%)
- obstruction: herniation, stenosis (skin and abdominal wall), adhesive bands, volvulus
- peri-ileostomy abscess and fistula
- skin irritation
- prolapse or retraction
- diarrhea (excessive output)

Figure 19. Ostoimes

Why Fistulae Stay Open
FRIENDO
- Foreign body
- Radiation
- Infection
- Epithelialization
- Neoplasim
- Distal obstruction (most common)
- Others: increased flow; steroids (may inhibit closure, usually will not maintain fistula)

Colostomy/Ileostomy
- Connection of proximal limb of colon or ileum to abdominal wall skin
- Mucous Fistula
- Connection of distal limb of colon to abdominal wall skin
- Ileal Conduit
- Connection of bowel to ureter proximally and abdominal wall distally to drain urine

Figure 20. End vs. loop colostomy

**Anorectum**

## Hemorrhoids

### Etiology
- Vascular and connective tissue complexes form a plexus of dilated veins (cushion)
  - Internal: Superior hemorrhoidal veins, above dentate line, portal circulation
  - External: Inferior hemorrhoidal veins, below dentate line, systemic circulation

### Risk Factors
- Increased intra-abdominal pressure: chronic constipation, pregnancy, obesity, portal hypertension, heavy lifting

### Clinical Features and Treatment
- **Internal Hemorrhoids:**
  - Engorged vascular cushions usually at 3, 7, 11 o'clock positions (patient in lithotomy position)
  - Painless rectal bleeding, anemia, prolapse, mucus discharge, pruritus, burning pain, rectal fullness:
    - **1st degree:** bleed but do not prolapse through the anus
      - Treatment: high fiber/bulk diet, sitz baths, steroid cream, paresol (Anusol®), rubber band ligation, sclerotherapy, photocoagulation
    - **2nd degree:** bleed, prolapse with straining, spontaneous reduction
      - Treatment: same as 2nd degree, but may require closed hemorrhoidectomy
    - **3rd degree:** bleed, prolapse, requires manual reduction
      - Treatment: closed hemorrhoidectomy
    - **4th degree:** bleed, permanently prolapsed, cannot be manually reduced
      - Treatment: closed hemorrhoidectomy
- **External Hemorrhoids:**
  - Dilated venules usually mildly symptomatic
  - Pain after bowel movement, associated with poor hygiene
  - Medical treatment: dietary fiber, stool softeners, steroid cream (short course), paresol (Anusol®), avoid prolonged straining
  - Thrombosed hemorrhoids are very painful:
    - Resolve within 2 wk, may leave excess skin = perianal skin tag
    - Treatment: consider surgical decompression within first 48 h of thrombosis, otherwise medical treatment

### Table 17. Signs and Symptoms of Internal vs. External Hemorrhoids

## Anal Fissures

### Definition
- Tear of anal canal below dentate line (very sensitive squamous epithelium)
- 90% posterior midline, 10% anterior midline
- If off midline: consider other possible causes such as IBD, STIs, TB, leukemia or anal carcinoma
- Repetitive injury cycle after first tear:
  - Sphincter spasm occurs preventing edges from healing and leads to further tearing
  - Ischemia may ensue and contribute to chronicity

### Etiology
- Forceful dilation of anal canal: large, hard stools and irritant diarrheal stools
- Tightening of anal canal secondary to nervousness/pain leads to further tearing
- Others: habitual use of cathartics, childbirth

### Clinical Features
- Acute fissure:
  - Very painful bright red bleeding especially after bowel movement, sphincter spasm on limited DRE
  - Treatment is conservative: stool softeners, bulking agent, sitz baths (heals 90%)
- Chronic fissure (anal ulcer):
  - Triad: fissure, sentinel skin tags, hypertrophied papillae
• treatment:
  • stool softeners, bulking agents, sitz baths
  • topical nitroglycerin or nifedipine: increases local blood flow, promoting healing and relieves sphincter spasm
  • lateral internal anal sphincterotomy (most effective): objective is to relieve sphincter spasm → increases blood flow and promotes healing; but 5% chance of fecal incontinence therefore not commonly done
  • alternative treatment:
    • botulinum toxin: inhibits release of acetylcholine (ACh), reducing sphincter spasm

### Anorectal Abscess

**Definition**
- infection in one or more of the anal spaces
- usually bacterial infection of blocked anal gland at the dentate line
  - *E. coli, Proteus, Streptococci, Staphylococci, Bacteroides, anaerobes*

**Clinical Features**
- throbbing pain that may worsen with straining and ambulation
- abscess can spread vertically downward (perianal), vertically upward (supralevator) or horizontally (ischiorectal)
- tender perianal/rectal mass on exam

**Treatment**
- incision and drainage
  - curative in 50% of cases
  - 50% develop anorectal fistulas
  - may require antibiotics if diabetic, heart murmur or cellulitis

### Fistula-In-Ano

**Definition**
- anal fistula from rectum to perianal skin
- an inflammatory tract with internal os at dentate line, external os on skin

**Etiology**
- see *Fistula, GS37*
- same perirectal process as an anal abscess, therefore usually associated with an abscess
- other causes: post-op, trauma, anal fissure, malignancy, radiation proctitis

**Clinical Features**
- intermittent or constant purulent discharge from perianal opening
- pain
- palpable cord-like tract
**Pilonidal Disease**

**Definition**
- chronic recurring abscess or chronic draining sinus in sacrococcygeal area

**Epidemiology**
- occurs most frequently in young men age 15–40 yr; rare in >50 yr

**Etiology**
- obstruction of the hair follicles in this area → formation of cysts, sinuses or abscesses

**Clinical Features**
- asymptomatic until acutely infected, then pain/tenderness, purulent discharge, ininspissated hair

**Treatment**
- acute abscess:
  - I&D (often performed by primary care doctors)
  - wound packed open
  - 40% develop chronic pilonidal sinuses
- surgery:
  - indication: failure of healing after I&D, recurrent disease, complex disease
  - pilonidal cystotomy: excision of sinus tract and cyst; wound closed by secondary intention, primary closure with tissue flap, or marsupialization (cyst edge sewn to surrounding tissue to leave sinus tract open)

**Rectal Prolapse**

**Definition**
- protrusion of some or all of rectal mucosa through external anal sphincter

**Epidemiology**
- extremes of ages: <5 yr old and >5th decade
- 85% women

**Etiology**
- lengthened attachment of rectum secondary to constant straining
- 2 types:
  1. false/partial/mucosal: protrusion of mucosa only, radial furrows at junction with anal skin; most common type of rectal prolapse in childhood
  2. true/complete (most common); full thickness extrusion of rectal wall, concentric folds in:
     - first degree: prolapse includes mucocutaneous junction
     - second degree: without involvement of mucocutaneous junction
     - third degree (internal intussusception): prolapse is internal, concealed, or occult
Risk Factors
- gynecological surgery
- chronic neurologic/psychiatric disorders affecting motility

Clinical Features
- extrusion of mass with increased intra-abdominal pressure:
  - straining, coughing, laughing, Valsalva
- difficulty in bowel regulation:
  - tenesmus, constipation, fecal incontinence
- permanently extruded rectum with excoriation, ulceration and constant soiling
- may be associated with urinary incontinence or uterine prolapse

Treatment
- Type I:
  - conservative: gentle manual reduction of prolapsed area, especially in children
  - mucosectomy with excision of redundant mucosa, mostly in adults
- Type II:
  - conservative: reduce if possible
  - surgery: abdominal, perineal, transsacral approaches

Anal Neoplasms

ANAL CANAL

Squamous Cell Carcinoma (SCC) of Anal Canal (above dentate line)
- most common tumour of anal canal (75%)
- anus prone to human papilloma virus (HPV) infection, therefore at risk for anal squamous intraepithelial lesions (ASIL)
  - high grade squamous intraepithelial lesion (HSIL) and low grade squamous intraepithelial lesion (LSIL) terminology used
- clinical features: anal bleeding, pain, mass, ulceration, pruritus; 25% asymptomatic
- treatment: chemotherapy ± radiation ± surgery
- prognosis: 80% 5-yr survival

Malignant Melanoma of Anal Canal
- 3rd most common site for primary malignant melanoma after skin, eyes
- aggressive, distant metastases common at time of diagnosis
- treatment: wide excision or APR ± chemoradiation
- prognosis: <5% 5-yr survival

ANAL MARGIN
- clinical features and treatment as for skin tumours elsewhere
- squamous and basal cell carcinoma, Bowen's disease (SCC in situ) and Paget's disease

Liver

Figure 26. Anatomy of liver
Liver Cysts

SIMPLE CYSTS
- most common type of liver cyst, may have multiple simple cysts
- clinical features: usually asymptomatic, if large may present with pain or mass; diagnose with U/S
- treatment: generally not required for simple cysts unless very large
- complications: intracystic hemorrhage (may be confused with complex cysts)

POLYCYSTIC LIVER DISEASE
- progressive condition where cysts replace much of the liver
- 50% associated with polycystic kidney disease
- treatment: if symptomatic treat by partial liver resection or by creating drainage for cysts

CHOLEDOCHAL CYSTS
- congenital malformations of pancreaticobiliary tree; majority present before age 10 yr
- 5 types, most extreme form called Caroli’s disease (multiple cystic dilations in intrahepatic ducts)
- clinical features: recurrent abdominal pain, intermittent jaundice, RUQ mass, cholangitis, pancreatitis
- diagnosis: U/S, CT, transhepatic cholangiography, LFTs
- treatment:
  - high risk of malignancy, current treatment is complete excision of cysts
  - abnormal pancreaticobiliary junction is associated with increased risk of malignancy
  - liver transplant indicated if cyst involves intrahepatic bile ducts (Caroli’s disease)
- complications of choledochal cysts: biliary cirrhosis, portal hypertension, rupture, cholangiocarcinoma

HYDATID LIVER CYSTS (CYSTIC ECHINOCOCCOSIS)
- etiology:
  - infection with parasite Echinococcus granulosus commonly found in Southern Europe, Middle East, Australasia, South America
  - associated with exposure to dogs, sheep and cattle
- clinical features:
  - asymptomatic mass (most often) or chronic pain, hepatomegaly; if large may compress inferior vena cava
  - rupture can cause biliary colic, jaundice, cholangitis, pancreatitis, or anaphylactic reaction
- investigations:
  - detection of anti-Echinococcus Ab (IgG) using ELISA
  - U/S, CT: presence of mass, often calcified
  - needle biopsy
- treatment:
  - medical: albendazole (anti-helminthic) – cure up to 30%
  - surgical (risk of spillage into abdomen):
    - conservative: open endocystectomy or PAIR (Percutaneous Aspiration, Injection of protoscolicidal agent, Re-aspiration)
    - radical: partial hepatectomy or total pericystectomy

CYSTADENOMA (PREMALIGNANT)/CYSTADENOCARCINOMA
- clinical features:
  - appear as complex cysts on imaging: internal septae, papillary projections, irregular lining
- all complex, multiloculated cysts (except echinococcal) should be excised because of malignancy risk

Liver Abscesses

Etiology
- types:
  - pyogenic (bacterial): most common etiology; most often polymicrobial – E. coli, Klebsiella, Proteus, Strep. milleri
  - parasitic (amoebic): Entamoeba histolytica
  - fungal: Candida
- sources: direct spread from biliary tract infection, portal spread from GI infection, systemic infection (e.g. endocarditis)

Clinical Features
- fever, malaise, chills, anorexia, weight loss, abdominal pain, nausea
- RUQ tenderness, hepatomegaly, jaundice
Investigations
- leukocytosis, anemia, elevated liver enzymes, hemagglutination titres for *Entamoeba* antibodies
- U/S, CXR (right basal atelectasis/effusion), CT, cyst aspiration with C&S

Treatment
- treat underlying cause
- generally will treat initially with antibiotics alone and add surgical or percutaneous drainage and IV antibiotics for larger abscesses (initially ceftriaxone + metronidazole or piperacillin/tazobactam)

Prognosis
- overall mortality 15% – higher rate if delay in diagnosis, multiple abscesses, malnutrition

Neoplasms

**BENIGN LIVER NEOPLASMS**

**Hemangioma (cavernous)**
- pathogenesis: most common benign hepatic tumour; results from malformation of angioblastic fetal tissue
- risk factors: F:M = 3:1, steroid therapy, estrogen (exogenous, pregnancy)
- clinical features:
  - usually small and asymptomatic, larger tumours may produce pain or compress nearby structures
  - shock if ruptured (very rare), consumptive coagulopathy if giant (in children)
- investigations:
  - contrast CT (well-demarcated hypodense mass with peripheral enhancement and delayed venous emptying), U/S (homogenous hyperechoic mass), arteriography (rarely used; "cotton wool" appearance), RBC scan
  - biopsy may result in hemorrhage
- treatment:
  - usually none unless tumour bleeds or is symptomatic, then excision by lobectomy or enucleation

**Focal Nodular Hyperplasia**
- pathogenesis: unclear, may be regenerative response to hyperperfusion from anomalous arteries at centre of nodule
- risk factors: female, age 20-50
- clinical features: asymptomatic, rarely grows or bleeds, no malignant potential
- investigations: central stellate scar on CT scan; technetium-99 scan is helpful
- treatment: may be difficult to distinguish from adenoma/fibrolamellar HCC (malignant potential) → often resected

**Adenoma**
- definition: benign glandular epithelial tumour
- risk factors: female, age 20-50, estrogen (OCP, pregnancy)
- clinical features: asymptomatic, 25% present with RUQ pain or mass
- investigations: CT (well-demarcated masses, often heterogeneous, isodense on non-contrast CT, peripheral enhancement/isodense/hypodense on contrast CT), U/S, biopsy (tendency to bleed following biopsy)
- treatment:
  - stop anabolic steroids or OCP
  - excise, especially if large (>5 cm), due to risk of transformation to hepatocellular carcinoma and spontaneous rupture/hemorrhage
  - smaller lesions can be effectively treated with embolization

**MALIGNANT LIVER NEOPLASMS**

**Primary**
- usually hepatocellular carcinoma (HCC)/hepatoma
- others include angiosarcoma, hepatoblastoma, hemangioendothelioma
- epidemiology: 3rd leading cause of cancer death worldwide, 9th in United States; highest in Africa, China, Taiwan
- risk factors:
  - chronic liver inflammation: chronic hepatitis B (inherently oncogenic) and C, cirrhosis (especially macronodular), hemochromatosis, α1-anti-trypsin deficiency
  - medications: OCPs (3x increased risk), steroids
  - smoking, alcohol, Betel nuts
  - chemical carcinogens (aflatoxin, microcystin, vinyl chloride – associated with angiosarcoma)
- clinical features:
  - RUQ discomfort, right shoulder pain
  - jaundice, weakness, weight loss, ± fever (if central tumour necrosis)
  - hepatomegaly, bruist, hepatic friction rub

Secondary liver metastases are common in many cancers, with some studies showing a prevalence of 40-50% amongst patients with extrahepatic cancers. They commonly arise from breast, lung and colorectal cancers. For metastases secondary to colorectal cancer, surgical resection offers the greatest likelihood of cure.
Liver Transplantation

*Leading cause in adults; **leading cause in children

Clinical Indications
- early referral for transplant should be considered for all patients with progressive liver disease not responsive to medical therapy, especially decompensated cirrhosis, unresectable primary liver cancers and fulminant hepatic failure
- end-stage liver disease with life expectancy <1 yr and if no other therapy is appropriate
- progressive jaundice, refractory ascites, spontaneous hepatic encephalopathy, recurrent sepsis, fulminant hepatic failure
- recurrent variceal hemorrhage, coagulopathy, severe fatigue

Criteria for Transplantation
- Model for End-Stage Liver Disease (MELD): considers probability of death within 3 mo if patient does not receive transplant; based on creatinine, bilirubin, INR; MELD scores from 6-40 used to prioritize liver allocation
- Child-Turcotte-Pugh Score: patient must have ≥7 points (Class B)

Contraindications
- active alcohol/substance abuse
- extrahepatic malignancy within 5 yr
- advanced cardiopulmonary disease

Liver Mass

**Differential Diagnosis of Metastatic Liver Mass**
- Some GU Cancers Produce Bumpy Lumps:
  - Stomach
  - Genitourinary cancers
  - Kidney, ovary, uterus
- Colon
- Pancreas
- Breast
- Lung

**Characteristics of Metastatic Liver Mass**
- Not poorly differentiated
- No systemic symptoms
- No extrahepatic or extrapulmonary metastases
- If the possibility of “curative” resection

**Staging Criteria for Hepatocellular Carcinoma**
- Milan Criteria
  - 1 tumour ≤5 cm
  - Up to 3 tumours each ≤3 cm
- UCSF Criteria
  - 1 tumour ≤5 cm
  - Up to 3 tumours each ≤4.5 cm, total diameter ≤8 cm
- Toronto Criteria
  - No tumour size of number restrictions
  - Not poorly differentiated

*Each criteria assumes no extrahepatic and no macrovascular invasion.

**Liver Mass**

- Liver metastases: GI (colorectal most common), lung, breast, pancreas, ovary, uterus, kidney, gallbladder
- Prognosis:
  - 5-yr survival: all patients – 5%; patients undergoing complete resection – 11-40%

**Clinical Indications**
- early referral for transplant should be considered for all patients with progressive liver disease not responsive to medical therapy, especially decompensated cirrhosis, unresectable primary liver cancers and fulminant hepatic failure
- end-stage liver disease with life expectancy <1 yr and if no other therapy is appropriate
- progressive jaundice, refractory ascites, spontaneous hepatic encephalopathy, recurrent sepsis, fulminant hepatic failure
- recurrent variceal hemorrhage, coagulopathy, severe fatigue

**Criteria for Transplantation**
- Model for End-Stage Liver Disease (MELD): considers probability of death within 3 mo if patient does not receive transplant; based on creatinine, bilirubin, INR; MELD scores from 6-40 used to prioritize liver allocation
- Child-Turcotte-Pugh Score: patient must have ≥7 points (Class B)

**Contraindications**
- active alcohol/substance abuse
- extrahepatic malignancy within 5 yr
- advanced cardiopulmonary disease

**Staging Criteria for Hepatocellular Carcinoma**

Clinical Features
- asymptomatic (80%):
  - most do NOT require treatment
  - consider cholecystectomy if: increased risk of malignancy (choledochal cysts, Caroli’s disease, porcelain or calcified gallbladder), sickle cell disease, pediatric patient, bariatric surgery, diabetes, immunosuppression

cholelithiasis

Definition
- the formation of gallstones

Pathogenesis
- imbalance of cholesterol and its solubilizing agents (bile salts and lecithin)
- excessive hepatic cholesterol secretion → bile salts and lecithin are “overloaded” → supersaturated cholesterol can precipitate and form gallstones
- North America: cholesterol stones (80%), pigment stones (20%)

Risk Factors
- cholesterol stones:
  - obesity, age <50
  - estrogens: female, multiparity, OCPs
  - ethnicity: First Nations heritage (especially Pima Indians) > Caucasian > Black
  - terminal ileal resection or disease (e.g. Crohn’s disease)
  - impaired gallbladder emptying: starvation, TPN, DM
  - rapid weight loss: rapid cholesterol mobilization and biliary stasis
- pigment stones (contain calcium bilirubinate):
  - cirrhosis
  - chronic hemolysis
  - biliary stasis (strictures, dilation, biliary infection)
  - protective factors: statins, vitamin C, coffee

Post-op Complications
- primary non-function (graft failure): urgent re-transplantation is indicated
- acute and chronic rejection, ischemia-reperfusion injury
- vascular: hepatic artery or portal vein thrombosis, IVC obstruction
- biliary complications: fever, increasing bilirubin and ALP
- complications related to immunosuppression: hypertension, renal disease, diabetes, obesity, hyperlipidemia, osteoporosis, malignancy, neurologic complications, infection (leading cause of mortality following transplant)

Prognosis
- patient survival at 1 yr: 85%
- graft survival at 1 yr: >80%, at 5 yr: 60-70%

© Merry Shiyu Wang 2012
• biliary colic (10-25%)
• cholecystitis
• cholelithiasis (8-15%)
• cholangitis
• gallstone pancreatitis (see Acute Pancreatitis, GS50)
• gallstone ileus

Investigations
• U/S – diagnostic procedure of choice:
  ▪ image for signs of inflammation, obstruction, localization of stones
• ERCP (endoscopic retrograde cholangiopancreatography):
  ▪ visualization of upper GI tract, ampullary region, biliary and pancreatic ducts
  ▪ method for treatment of CBD stones in periampullary region
  ▪ complications: traumatic pancreatitis (1-2%), pancreatic or biliary sepsis
• MRCP (magnetic resonance cholangiopancreatography):
  ▪ same information gained as ERCP but non-invasive
  ▪ cannot be used for therapeutic purposes
• PTC (percutaneous transhepatic cholangiography):
  ▪ injection of contrast via needle passed through hepatic parenchyma
  ▪ useful for proximal bile duct lesions or when ERCP fails or not available
  ▪ requires prophylactic antibiotics
  ▪ contraindications: coagulopathy, ascites, peri/intrahepatic sepsis, disease of right lower lung or pleura
  ▪ complications: bile peritonitis, chylothorax, pneumothorax, sepsis, hemobilia
• HIDA scan (hepatobiliary imino-diacetic acid scan):
  ▪ used less commonly
  ▪ radioisotope technetium-99 injected into a vein is excreted in high concentrations into bile, allowing visualization of the biliary tree
  ▪ does not visualize stones; diagnosis by seeing occluded cystic duct or CBD

Pathogenesis

Clinical Features
• steady, severe dull pain in epigastrium or RUQ for minutes to hours, crescendo-decrescendo pattern
• may present with chest pain
• frequently occurs at night or after fatty meal, not after fasting
• can radiate to right shoulder or scapula
• patients often restless
• no peritoneal findings, no systemic signs

Investigations
• normal blood work: CBC, electrolytes, LFTs, bilirubin, amylase
• U/S shows cholelithiasis, may show stone in cystic duct

Treatment
• analgesia, rehydration during colic episode
• elective cholecystectomy (95% success):
  ▪ complications: CBD injury (0.3-0.5%), hollow viscus injury, bile peritonitis, vessel injury
  ▪ laparoscopic cholecystectomy is the standard of care, no benefit to delaying surgery
  ▪ risk of open cholecystectomy higher in emergency situations

Acute Cholecystitis

Pathogenesis
• inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann’s pouch
• no cholelithiasis in 5-10% (see Acalculous Cholecystitis, GS47)

Clinical Features
• often have history of biliary colic
• severe constant (hours to days) epigastric or RUQ pain, anorexia, nausea, vomiting, low grade fever (<38.5°C)
• focal peritoneal findings: Murphy’s sign, palpable, tender gallbladder (in 33%)
• Boas’ sign: right subscapular pain

Investigation
• bloodwork: elevated WBC and left shift, mildly elevated bilirubin, AST, ALT and ALP
• U/S: 98% sensitive, consider HIDA scan if U/S negative

Acalculous Cholecystitis
• Acute or chronic cholecystitis in the absence of stones, typically due to gallbladder ischemia, stasis
• Risk factors: DM, immunosuppression, ICU admission, trauma patient, TPN, sepsis
• Clinical features same as Acute cholecystitis, occurs in 20% of cases of acute cholecystitis
• Investigations: U/S shows sludge in gallbladder, other U/S features of cholecystitis (see above), CT or HIDA scan
• Treatment: broad-spectrum antibiotics, cholecystectomy, if patient unstable → cholecystostomy

Rouviere’s Sulcus
Fissure between right lobe and caudate process of liver. Keeping dissection anterior to this landmark prevents bile duct injury.

Critical View of Safety
Space between the gallbladder and liver clear of any structures other than the cystic artery.
Complications
- gallbladder mucocele (hydrops): long term cystic duct obstruction results in mucous accumulation in gallbladder (clear fluid)
- gangrene (20%), perforation (2%): result in abscess formation or peritonitis
- empyema of gallbladder: suppurative cholecystitis, pus in gallbladder + sick patient
- cholecystoenteric fistula, from repeated attacks of cholecystitis, can lead to gallstone ileus
- emphysematous cholecystitis: bacterial gas present in gallbladder lumen, wall or pericholecystic space (risk in diabetic patient)
- Mirizzi syndrome: extra-luminal compression of CBD/CHD due to large stone in cystic duct

Treatment
- admit, hydrate, NPO, NG tube (if persistent vomiting from associated ileus), analgesics once diagnosis is made
- antibiotics:
  - cefazolin if uncomplicated cholecystitis
- cholecystectomy:
  - early (within 72 h) vs. delayed (after 6 wk)
    - equal morbidity and mortality
    - early cholecystectomy preferred: shorter hospitalization and recovery time, no benefit to delaying surgery
    - emergent OR indicated if high risk, e.g. emphysematous
- laparoscopic is standard of care (convert to open for complications or difficult case)
- laparoscopic: reduced risk of wound infections, shorter hospital stay, reduced post-op pain, increased risk of bile duct injury
- intra-operative cholangiography (IOC):
  - indications: clarify bile duct anatomy, obstructive jaundice, history of biliary pancreatitis, small stones in gallbladder with a wide cystic duct (>15 mm), single faceted stone in gallbladder, bilirubin >137 µmol/L
  - percutaneous cholecystostomy tube: critically ill or if general anesthetic contraindicated

Acalculous Cholecystitis

Definition
- acute or chronic cholecystitis in the absence of stones

Pathogenesis
- typically due to gallbladder ischemia, stasis

Risk Factors
- DM, immunosuppression, ICU admission, trauma patient, TPN, sepsis

Clinical Features
- see Acute Cholecystitis, GS46
- occurs in 20% of cases of acute cholecystitis

Investigations
- U/S: shows sludge in gallbladder, other U/S features of cholecystitis (see Acute Cholecystitis, GS46)
- CT or HIDA scan

Treatment
- broad-spectrum antibiotics, cholecystectomy
- if patient unstable → cholecystostomy

Choledocholithiasis

Definition
- stones in common bile duct (CBD)

Clinical Features
- 50% asymptomatic
- often have history of biliary colic
- tenderness in RUQ or epigastrum
- acholic stool, dark urine, fluctuating jaundice
- primary vs. secondary stones:
  - primary: formed in bile duct, indicates bile duct pathology (e.g. benign biliary stricture, sclerosing cholangitis, choledochal cyst, cystic fibrosis)
  - secondary: formed in gallbladder (85% of cases in U.S.)
Investigations
• CBC: usually normal; leukocytosis suggests cholangitis
• LFTs: increased AST, ALT early in disease, increased bilirubin (more sensitive), ALP, GGT later
• amylase/lipase: to rule out gallstone pancreatitis
• U/S: intra-extra-hepatic duct dilatation; differential diagnosis is choledochal cyst
• ERCP, PTC
• MRCP (90% sensitive, almost 100% specific, not therapeutic)

Complications
• cholangitis, pancreatitis, biliary stricture and biliary cirrhosis

Treatment
• if no evidence of cholangitis: treat with ERCP for CBD stone extraction possibly followed by elective cholecystectomy in 25% of patients

Acute Cholangitis

Pathogenesis
• obstruction of CBD leading to biliary stasis, bacterial overgrowth, suppuration and biliary sepsis – may be life-threatening, especially in elderly

Etiology
• choledocholithiasis (60%), stricture, neoplasm (pancreatic or biliary), extrinsic compression (pancreatic pseudocyst or pancreatitis), instrumentation of bile ducts (PTC, ERCP), biliary stent
• organisms: E. coli, Klebsiella, Pseudomonas, Enterococcus, B. fragilis, Proteus

Clinical Features
• Charcot's triad: fever, RUQ pain, jaundice
• Reynold's pentad: fever, RUQ pain, jaundice, shock, confusion
• may have nausea, vomiting, abdominal distention, ileus, acholic stools, tea-coloured urine (elevated direct bilirubin)

Investigations
• CBC: elevated WBC + left shift
• may have positive blood cultures
• LFTs: obstructive picture (elevated ALP, GGT and conjugated bilirubin, mild increase in AST, ALT)
• amylase/lipase: rule out pancreatitis
• U/S: intra-extra-hepatic duct dilatation

Treatment
• initial: NPO, fluid and electrolyte resuscitation, ± NG tube, IV antibiotics (treats 80%)
• decompression:
  ▪ ERCP + sphincterotomy: diagnostic and therapeutic
  ▪ PTC with catheter drainage: if ERCP not available or unsuccessful
  ▪ laparotomy with CBD exploration and T-tube placement if above fails
• all patients should also have a cholecystectomy, unless contraindicated

Prognosis
• suppurative cholangitis mortality rate: 50%

Gallstone Ileus

Pathogenesis
• repeated inflammation causing a cholecystoenteric fistula (usually duodenal) → large gallstone enters the gut and impacts at or near the ileocecal valve, causing a true bowel obstruction (note: ileus is a misnomer in this context)

Clinical Features
• crampy abdominal pain, nausea, vomiting (see Bowel Obstruction, GS24)

Investigations
• AXR: dilated small intestine, air fluid levels, may reveal radiopaque gallstone, air in biliary tree (pneumobilia) (40%)
• CT: biliary tract air, obstruction, gallstone in intestine
• Rigler's triad: pneumobilia (air in biliary tree), small bowel obstruction (partial or complete), gallstone (usually in right iliac fossa)

American Society of Gastrointestinal Endoscopy 2010 Predictors for Risk of CBD Stones:
• Very strong:
  ▪ CBD stone on ultrasound
  ▪ Clinical ascending cholangitis
  ▪ Bilirubin >68 µmol/L
• Strong:
  ▪ CBD dilated >6 mm on ultrasound
  ▪ Bilirubin 31-68 µmol/L
• Moderate:
  ▪ Abnormal liver test (besides bilirubin)
  ▪ Age >55 yr
  ▪ Clinical gallstone pancreatitis

Charcot’s Triad
Fever, RUQ pain, jaundice.

Reynold’s Pentad
Fever, RUQ pain, jaundice, shock, confusion.

Common Bacteria in Biliary Tract
KEEPS
Klebsiella
Enterococcus
E. Coli, Enterobacter
Proteus, Pseudomonas
Serratia

Bouvetre’s Syndrome
Gastric outlet/duodenal obstruction caused by a large gallstone passing through a cholecystogastric or cholecystoduodenal fistula.

Rigler’s Triad of Gallstone Ileus:
• Pneumobilia
• Small bowel obstruction
• Gallstone
Treatment
- fluid resuscitation, NG decompression
- surgery: enterolithotomy and removal of stone, inspect small and large bowel for additional proximal stones
- may close fistula surgically or manage expectantly (can resolve spontaneously)
- cholecystectomy either during enterolithotomy or after recovery if patient experiences gallbladder symptoms

Carcinoma of the Gallbladder

Risk Factors
- chronic symptomatic gallstones (70% of cases), old age, female, gallbladder polyps, porcelain gallbladder, chronic infection (Salmonella, Helicobacter), abnormal pancreaticobiliary duct junction

Clinical Features
- majority are adenocarcinoma
- may be incidental finding on elective cholecystectomy (~1% of elective cholecystectomies)
- many patients are asymptomatic until late
- local: vague RUQ pain, palpable RUQ mass
- Courvoisier’s gallbladder: an enlarged, often palpable gallbladder in a patient with carcinoma of the head of the pancreas; associated with jaundice due to obstruction of the common bile duct
- systemic: jaundice (50%) due to invasion of CBD or compression of CBD by pericholedochal nodes, weight loss, malaise, anorexia
- early local extension to liver, may extend to stomach, duodenum
- early metastasis common to liver, lung, bone

Investigations
- U/S: mural thickening, calcification, loss of interface between gallbladder and liver, fixed mass
- endoscopic U/S (EUS): good for distinguishing carcinomas from other diagnoses such as polyps, good for staging, allows sampling of bile for cytology
- abdominal CT: polypoid mass, mural thickening, liver invasion, nodal involvement, distant metastases
- MRI/MRCP: good for distinguishing benign and malignant polyps

Treatment
- if carcinoma of the gallbladder is suspected preoperatively, an open cholecystectomy should be considered to avoid tumour seeding of the peritoneal cavity
- confined to mucosa (rare): cholecystectomy
- beyond mucosa: cholecystectomy, en bloc wedge resection of 3-5 cm underlying liver, dissection of hepatoduodenal lymph nodes

Prognosis
- poor 5 yr survival (10%) as gallbladder carcinoma is often detected late
- better outcomes when detected incidentally following cholecystectomy

Cholangiocarcinoma

Definition
- malignancy of extra- or intrahepatic bile ducts

Risk Factors
- age 50-70, gallstones, ulcerative colitis, primary sclerosing cholangitis, choledochal cyst, Clonorchis sinensis infection (liver fluke), chronic intrahepatic stones (hepatolithiasis)

Clinical Features
- majority are adenocarcinomas
- gradual signs of biliary obstruction: jaundice, pruritus, dark urine, pale stools
- anorexia, weight loss, RUQ pain, Courvoisier’s sign (if CBD obstructed), hepatomegaly
- early metastases are uncommon, but commonly tumour grows into portal vein or hepatic artery
- Klatskin tumour: cholangiocarcinoma located at bifurcation of common hepatic duct

Investigations
- LFTs show obstructive picture
- U/S, CT: bile ducts usually dilated, but not necessarily
- ERCP or PTC: to determine resectability, for biopsies
- CXR, bone scan: for metastatic workup

Obstructive jaundice is the most common presenting symptom for cholangiocarcinoma.

Courvoisier’s Sign
Palpable, nontender distended gallbladder due to CBD obstruction. Present in 33% of patients with pancreatic carcinoma. The distended gallbladder could not be due to acute cholecystitis or stone disease because the gallbladder would actually be scarred and smaller, not larger.
Pathogenesis
- GALLSTONE PANCREATITIS (35% of acute pancreatitis)
  - upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
  - middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
  - lower third lesions: Whipple procedure
- unresectable lesions: stent or choledochojejunostomy (surgical bypass)

Complications
- severe hypocalcemia
- encephalopathy
- coagulopathy/DIC
- ARDS/sepsis/multiorgan failure
- diabetes
- pancreatic ascites/pancreatic pleural effusion
- granulation tissue
- pseudocyst (collection of pancreatic secretions >4 wk old surrounded by a defined wall of granulation tissue)
- abscess/infection, necrosis
- splenic/mesenteric portal vessel thrombosis or rupture
- diabetes
- ARDS/sepsis/multiorgan failure
- coagulopathy/DIC
- severe hypocalcemia

Treatment
- generally palliative
- if resectable: biliary drainage and wide excision margin
- upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
- middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
- lower third lesions: Whipple procedure
- unresectable lesions: stent or choledochojejunostomy (surgical bypass)

Prognosis
- radiotherapy useful for additional palliation, chemotherapy may be helpful
- the more proximal to the liver, the worse the prognosis
- overall 5-yr survival: 15%

Pancreas

Acute Pancreatitis
- see Gastroenterology, G44

GALLSTONE PANCREATITIS (35% of acute pancreatitis)

Pathogenesis
- obstruction of pancreatic duct by large or small gallstones and biliary sludge
- backup of pancreatic enzymes can cause autodigestion of the pancreas

Clinical Features (pancreatitis of any etiology)
- pain (epigastric pain radiating to back), nausea, vomiting, ileus, peritoneal signs, jaundice, fever
- Inglefinger's sign: pain worse when supine, better when sitting forward
- rarely may have coexistent cholangitis or pancreatic necrosis
- Ranson's criteria for determining prognosis of acute pancreatitis (see sidebar)

Investigations
- high amylase (higher than alcoholic pancreatitis), lipase, leukocytosis
- elevated ALT (>150 IU/L), AST strongly suggest gallstone etiology of pancreatitis
- U/S may show multiple stones (may have passed spontaneously), edematous pancreas
- CXR, AXR, CT (if severe to evaluate for complications)

Treatment
- supportive
- enteral nutrition
- NPO, hydration, analgesia and antibiotics for severe cases of necrotizing pancreatitis or signs of sepsis
- stone often passes spontaneously (~90%); usually no surgical management in uncomplicated acute pancreatitis
- cholecystectomy during same admission (25-60% recurrence if no surgery)
- may need urgent ERCP + sphincterotomy if failure of conservative management (benefits of early ERCP controversial)
- early ERCP if concomitant cholangitis
- surgical indications in acute pancreatitis (rare):
  - debridement and drain placement for necrotizing pancreatitis if refractory to medical management, if septic or in ICU without other sources of sepsis

Complications
- pseudocyst (collection of pancreatic secretions >4 wk old surrounded by a defined wall of granulation tissue)
- abscess/infection, necrosis
- splenic/mesenteric portal vessel thrombosis or rupture
- pancreatic ascites/pancreatic pleural effusion
- diabetes
- ARDS/sepsis/multiorgan failure
- coagulopathy/DIC
- encephalopathy
- severe hypocalcemia

Ranson's Criteria

Interpretation
- ≥2 = difficult course
- ≥3 = high mortality (>15%)

Efficacy of Neoadjuvant Chemoradiation, Followed by Liver Transplantation, for Perihilar Cholangiocarcinoma at 12 US Centers

Purpose: To determine the effectiveness of neoadjuvant chemoradiation and liver transplantation for unresectable perihilar cholangiocarcinoma and to determine the appropriateness of the United Network of Organ Sharing/Organ Procurement and Transplantation Network (UNOS/OPTN) criteria for model of end-stage liver disease (MELD) exception for patients with this disease.

Methods: Study conducted from 1993-2010 in 12 transplant centers. 287 patients included.

Results: Median follow-up was 2.5 yr. 43% of patients (n = 122) died after a median of 1.2 yr from presentation, and of these, 60 died pretransplant. Post-transplant, 43 patients had recurrences and 62 died. Recurrence-free survival at 2, 5, and 10 yr were 38%, 35%, and 59%, respectively. Intention-to-treat survival rates at 2 and 5 yr were 68% and 53%, respectively. 25% of patients left the waiting list after a median of 4.6 mo. The waiting list drop-out rate increased by an average of 11.5% every 3 mo. Patients who received transplantation outside of the criteria for MELD exception or who had a malignancy within 5 yr had significantly worse recurrence-free survival compared to those who met the criteria (HR = 2.98, 95% CI: 1.79, 4.95). Recurrence-free survival at 5 yr was shorter for patients with tumors >3 cm versus <3 cm (p < 0.001).

Conclusions: Neoadjuvant chemoradiation and liver transplantation are effective treatments for unresectable perihilar cholangiocarcinoma. Furthermore, the UNOS/OPTN criteria for MELD exception appear to be appropriate.
Chronic Pancreatitis

- see also Gastroenterology, G46

Surgical Treatment
- treatment is generally medical
- indications for surgery:
  - failure of medical treatment
  - debilitating abdominal pain
  - pseudocyst complications: persistence, hemorrhage, infection, rupture
  - CBD obstruction (e.g. strictures), duodenal obstruction
  - pancreatic fistula, variceal hemorrhage secondary to splenic vein obstruction
  - rule out pancreatic cancer (present in 15% of chronic pancreatitis treated surgically)
  - anatomical abnormality causing recurrent pancreatitis
- pre-op CT and/or ERCP are mandatory to delineate anatomy
- minimally invasive options:
  - endoscopic pancreatic duct decompression: less effective than surgery
  - extracorporeal shockwave lithotripsy: if pancreatic duct stones
  - celiac plexus block: lasting benefit in 30% patients, less effective in those <45 yr or with prior pancreatic surgery
- surgical options:
  - drainage procedures: only effective if ductal system is dilated
    - Puestow procedure (lateral pancreaticojejunostomy): improves pain in 80% of patients
  - pancreatectomy: best option in absence of dilated duct
    - proximal disease: Whipple procedure (pancreaticoduodenectomy) – pain relief in 80%
    - distal disease: distal pancreatectomy ± Roux-en-Y pancreaticojejunostomy
  - total pancreatectomy: refractory disease
  - denervation of celiac ganglion and splanchnic nerves
- pseudocyst (often resolve spontaneously with pancreatic rest):
  - cyst wall must be mature prior to drainage (4-6 wk)
  - pseudoaneurysm an absolute contraindication to endoscopic drainage, must embolize first
  - percutaneous catheter drainage
  - surgical drainage (gold standard):
    - cystgastrostomy
    - cystenterostomy
    - resection
  - endoscopic drainage:
    - cystgastrostomy
    - cystduodenostomy
- consider biopsy of cyst wall to rule out cystadenocarcinoma

Pancreatic Cancer

Epidemiology
- fourth most common cause of cancer-related mortality in both men and women in Canada
- M:F = 1.3:1, average age: 50-70

Risk Factors
- increased age
- smoking: 2-5x increased risk, most clearly established risk factor
- high fat/low fibre diets, heavy alcohol use
- obesity
- DM, chronic pancreatitis
- partial gastrectomy, cholecystectomy
- chemicals: betanaphthylamine, benzidine
- African descent

Clinical Features
- head of the pancreas (70%):
  - weight loss, obstructive jaundice, vague constant mid-epigastric pain (often worse at night, may radiate to back)
  - painless jaundice (occurs more often with peri-ampullary), Courvoisier’s sign (see sidebar GS49)
  - palpable tumour mass → generally incurable
- body or tail of pancreas (30%):
  - tends to present later and usually inoperable
  - weight loss, vague mid-epigastric pain
  - <10% jaundiced
  - sudden onset diabetes

Investigations
- serum chemistry is non-specific, can have elevated ALP and bilirubin >300 µmol/L
- CA 19-9 (most useful serum marker of pancreatic cancer)
- U/S, contrast CT (also evaluates metastasis and resectability), ERCP, MRI, MRCP
Pathology
- ductal adenocarcinoma: most common type (75-80%); exocrine pancreas
- intraductal papillary mucinous neoplasm (IPMN)
- other: mucinous cystic neoplasm (MCN), acinar cell carcinoma, islet-cell (insulinoma, gastrinoma, VIPoma, glucagonoma, somatostatinoma)
- see Surgical Endocrinology, GS60 for insulinoma

Treatment
- resectable (20% of pancreatic cancer)
  - no involvement of liver, peritoneum or vasculature (hepatic artery, SMA, SMV, portal vein, IVC, aorta), no distant metastasis
  - Whipple procedure (pancreaticoduodenectomy) for cure – 5% mortality
  - distal pancreatectomy ± splenectomy, lymphadenectomy if carcinoma of midbody and tail of pancreas
- borderline resectable
  - tumours that abut the SMA, SMV, portal vein, hepatic artery, or celiac artery
- non-resectable (palliative treatment)
  - relieve biliary/duodenal obstruction with endoscopic stenting or double bypass procedure (choledochointerostomy + gastroenterostomy)
  - chemotherapy (gemcitabine, folfirinox), radiotherapy – only slightly increase survival

Prognosis
- most important prognostic indicators are lymph node status, size >3 cm, perineural invasion (invasion of tumour into microscopic nerves of pancreas)
- overall 5-yr survival is 1%
- 20% 5-yr survival following resection
- median survival for unresectable disease: 8-12 mo if locally advanced, 3-6 mo if metastatic

</tbody>
</table>

Steps of a Whipple Resection (Pancreaticoduodenectomy):
1. Assessment of metastatic disease (all peritoneal surfaces)
2. Mobilization of the duodenum and head of the pancreas with identification of the superior mesenteric vein
3. Mobilization of the stomach and proximal duodenum, transection of the stomach or proximal duodenum
4. Dissection of the hepatoduodenal ligament with skeletonization of the porta hepatis
5. Cholecystectomy and division of the bile duct
6. Mobilization and division of the proximal jejunum
7. Transection of the pancreatic neck and division of any remaining attachments
8. Reconstruction of gastrointestinal continuity: pancreaticojejunostomy, hepaticejejunostomy, gastroduodenojunostomy

Removed:
- Common bile duct
- Gallbladder
- Duodenum
- Pancreatic head
- Distal stomach (sometimes)
**Spleen**

**Splenic Trauma**
- typically from blunt trauma (especially in people with splenomegaly)
- most common intra-abdominal organ injury in blunt trauma
- may have Kehr’s sign

**Treatment**
- non-operative:
  - in stable patients: extended bed rest with serial hematocrit levels, close monitoring for 3-5 d; pediatric guidelines for days of bed rest is grade plus 1 (i.e. grade 3 splenic laceration requires 4 d of bed rest)
  - hemostatic control
  - splenic artery embolization if patient stable and one of: active contrast extravasation, splenic pseudoaneurysm, hemoperitoneum
- operative:
  - splenorrhaphy (suture of spleen) ± splenic wrapping with hemostatic mesh – if patient hemodynamically stable, patient has stopped bleeding and laceration does not involve hilum
  - partial splenectomy, rarely performed due to risk of recurrent hemorrhage
  - total splenectomy if patient unstable or high-grade injury

**Splenectomy**

**Indications**
- splenic trauma (most common reason for splenectomy), hereditary spherocytosis, primary hypersplenism, chronic immune thrombocytopenia purpura (ITP), splenic vein thrombosis causing esophageal varices, splenic abscess, thrombotic thrombocytopenia purpura (TTP), sickle cell disease
- does not benefit all thrombocytopenic states (e.g. infection, most malignancies involving the bone marrow, drugs/toxins)
- probability of cure of ITP by splenectomy is 60-70%, may be predicted by response to IVIg

**Complications**
- short-term:
  - injury to surrounding structures (e.g. gastric wall, tail of pancreas)
  - post-op thrombocytosis, leukocytosis
  - thrombosis of portal, splenic, or mesenteric veins
  - subphrenic abscess
- long-term:
  - post-splenectomy sepsis (encapsulated organisms): 4% of splenectomized patients (highest risk in those <16 yr old)
    - 50% mortality
    - prophylaxis with vaccinations, ideally 2 wk pre- or post-op *(pneumococcal, H. influenzae and meningococcus)*
    - liberal use of penicillin especially in children <6 yr old
  - splenosis: intra-abdominal “seeding” of splenic tissue during removal
Benign Breast Lesions

NON-PROLIFERATIVE LESIONS
- also known as fibrocystic change, chronic cystic mastitis, mammary dysplasia
- benign breast condition characterized by fibrous and cystic changes in the breast
- no increased risk of breast cancer
- age 30 to menopause (and after if HRT used)
- clinical features:
  - breast pain, focal areas of nodularity or cysts often in the upper outer quadrant, frequently bilateral, mobile, varies with menstrual cycle, nipple discharge (straw-like, brown or green)
- treatment:
  - evaluation of breast mass and reassurance
  - if >40 yr old: mammography every 3 yr
  - no strong evidence for avoidance of xanthine-containing products (coffee, tea, chocolate, cola)
  - analgesia (ibuprofen, ASA)
  - for severe symptoms: OCP, danazol, bromocriptine

PROLIFERATIVE LESIONS – No Atypia

Fibroadenoma
- most common benign breast tumour in women under age 30
- risk of subsequent breast cancer is increased only if fibroadenoma is complex, there is adjacent atypia or a strong family history of breast cancer
- clinical features:
  - nodules: smooth, rubbery, discrete, well-circumscribed, non-tender, mobile, hormone dependent
  - unlike cysts, needle aspiration yields no fluid
- investigations:
  - core or excisional biopsy required
  - ultrasound and FNA alone cannot differentiate fibroadenoma from Phyllodes tumour
- treatment:
  - generally conservative: serial observation
  - consider excision if size 2-3 cm and growing on serial ultrasound (q6mo x 2 yr is usual follow-up), if symptomatic or patient preference

Intraductal Papilloma
- solitary intraductal benign polyp
- present as nipple discharge (most common cause of spontaneous, unilateral, bloody nipple discharge), breast mass, nodule on U/S
- can harbour areas of atypia or DCIS
- treatment: excision of involved duct to ensure no atypia

DDx for Breast Mass
Benign:
- Fibrocystic changes
- Fibroepithelial lesions (fibroadenoma most common; benign phyllodes also)
- Fat necrosis
- Papilloma/papillomatosis
- Galactocele
- Duct ectasia
- Ductal/lobular hyperplasia
- Sclerosing adenosis
- Lipoma
- Neurofibroma
- Granulomatous mastitis (e.g. TB, granulomatosis with polyangiitis, sarcoidosis)
- Abscess
- Silicone implant

Malignant:
- Breast ca (likely invasive, DCIS rarely forms a breast mass)
- Malignant phyllodes
- Angiosarcoma (rare)
Ductal Hyperplasia Without Atypia
- increased number of cells within the ductal space
- cells retain benign cytology
- no treatment required
- slightly increased cancer risk if moderate or florid hyperplasia

PROLIFERATIVE LESIONS – With Atypia
Atypical Hyperplasias
- can involve ducts (ductal hyperplasia with atypia) or lobules (lobular hyperplasia with atypia)
- cells lose apical-basal orientation
- increased risk of breast cancer
- diagnosis: core or excisional biopsy
- treatment: complete resection, risk modification (avoid exogenous hormones), close follow-up

OTHER LESIONS
Fat Necrosis
- uncommon, result of trauma (may be minor, positive history in only 50%), after breast surgery (i.e. reduction)
- firm, ill-defined mass with skin or nipple retraction, ± tenderness
- regresses spontaneously, but complete imaging ± biopsy to rule out carcinoma

Mammary Duct Ectasia
- obstruction of a subareolar duct leading to duct dilation, inflammation, and fibrosis
- may present with nipple discharge, bluish mass under nipple, local pain
- risk of secondary infection (abscess, mastitis)
- resolves spontaneously

Montgomery Tubercle
- Montgomery tubercles (or Morgagni tubercles) are papular projections at the edge of the areola
- obstruction of these glands can lead to inflammation or cystic collections (cyst of Montgomery aka retroareolar cyst)
- if signs of secondary infection, start treatment for mastitis
- resolves spontaneously in weeks to years

Abscess
- lactational (see Obstetrics, OB51) vs. periductal/subareolar
- unilateral localized pain, tenderness, erythema, subareolar mass, nipple discharge, nipple inversion
- rule out inflammatory carcinoma, as indicated
- treatment: initially broad-spectrum antibiotics and I&D, if persistent total duct excision (definitive)
- if mass does not resolve: U/S to assess for presence of abscess, core biopsy to exclude cancer, consider MRI

Breast Cancer
Epidemiology
- 2nd leading cause of cancer mortality in women (1st is lung cancer)
- 1/9 of women in Canada will be diagnosed with breast cancer in their lifetime
- 1/27 of women in Canada will die from breast cancer

Risk Factors
- gender (99% female)
- age (80% >40 yr old)
- important risk factors are prior history of breast cancer and/or prior breast biopsy (regardless of pathology)
- 1st degree relative with breast cancer (greater risk if relative was premenopausal)
- increased risk with high breast density, nulliparity, first pregnancy >30 yr old, menarche <12 yr old, menopause >55 yr old
- decreased risk with lactation, early menopause, early childbirth
- radiation exposure (e.g. mantle radiation for Hodgkin’s disease)
- >5 yr HRT
**Investigations**
- mammography
  - indications:
    - screening refer to Family Medicine, FM3
    - findings indicative of malignancy:
      - mass that is poorly defined, spiculated border
      - microcalcifications
      - architectural distortion
      - interval mammographic changes
      - normal mammogram does not rule out suspicion of cancer based on clinical findings
- other radiographic studies:
  - U/S: differentiate between cystic and solid
  - MRI: high sensitivity, low specificity
  - galactogram/ductogram (for nipple discharge): identifies lesions in ducts
  - metastatic workup as indicated (usually after surgery or if clinical suspicion of metastatic disease): bone scan, abdominal U/S, CXR (or CT chest/abdomen/pelvis), head CT (only if specific neurological symptoms)

**Diagnostic Procedures**
- needle aspiration: for palpable cystic lesions; send fluid for cytology if blood or cyst does not completely resolve
- U/S or mammography guided core needle biopsy (most common)
- fine needle aspiration (FNA): for palpable solid masses; need experienced practitioner for adequate sampling
- excisional biopsy: only performed as second choice to core needle biopsy; should not be done for diagnosis if possible

**Genetic Screening**
- consider testing for BRCA1/2 if:
  - patient diagnosed with breast AND ovarian cancer
  - strong family history of breast/ovarian cancer
  - family history of male breast cancer
  - young patient (<35 yr old)
  - bilateral breast cancer in patients <50 yr old

**Staging** (see Table 20)
- clinical:
  - tumour size by palpation, mammogram
  - nodal involvement by palpation
  - metastasis by physical exam, CXR and abdominal U/S (or CT chest/abdomen/pelvis), bone scan (usually done post-op if node-positive disease)
- pathological:
  - tumour size
  - grade: modified Bloom and Richardson score (I to III) – histologic, nuclear and mitotic grade
  - number of axillary nodes positive for malignancy out of total nodes resected, extranodal extension, sentinel node positive/negative
  - estrogen receptor (ER) + progesterone receptor (PR) testing
  - Her2Neu receptor testing
  - margins: negative, <1 mm, positive
  - lymphovascular invasion (LVI)
  - extensive in situ component (EIC): DCIS in surrounding tissue
  - involvement of dermal lymphatics (inflammatory) – automatically Stage IIIb

Pathology

- non-invasive (cannot penetrate basement membrane):
  - ductal carcinoma *in situ* (DCIS):
    - proliferation of malignant ductal epithelial cells completely contained within breast ducts, often multifocal
    - 80% non-palpable, detected by screening mammogram
    - risk of invasive ductal carcinoma in same breast up to 35% in 10 yr
  - treatment:
    - lumpectomy with wide excision margins + radiation (5-10% risk invasive cancer)
    - mastectomy if large area of disease, high grade or multifocal (risk of invasive cancer reduced to 1%)
    - possibly tamoxifen as an adjuvant treatment
    - 99% 5-yr survival

- lobular carcinoma *in situ* (LCIS):
  - neoplastic cells completely contained within breast lobule
  - no palpable mass, no mammographic findings, usually incidental finding on breast biopsy for another indication
  - treatment
    - clinical follow-up
    - chemotherapy (tamoxifen)
    - surgery (uncommon)
  - not a precursor lesion, but considered a risk factor for breast cancer development

- invasive:
  - invasive ductal carcinoma (most common 80%):
    - originates from ductal epithelium and infiltrates supporting stroma
    - characteristics: hard, scirrhouous, infiltrating tentacles, gritty on cross-section
  - invasive lobular carcinoma (8-15%):
    - originates from lobular epithelium
    - 20% bilateral (i.e. more often than infiltrating ductal carcinoma)
  - Paget’s disease (1-3%):
    - ductal carcinoma that invades nipple with scaling, eczematoid lesion
  - inflammatory carcinoma (1-4%):
    - ductal carcinoma that invades dermal lymphatics
    - most aggressive form of breast cancer
    - clinical features: erythema, skin edema, warm, swollen and tender breast ± lump
    - peau d’orange indicates advanced disease (IIb-IV)
  - male breast cancer (<1%):
    - most commonly invasive ductal carcinoma
    - often diagnosed at later stages
    - stage-for-stage similar prognosis to breast cancer in females
    - consider genetic testing
  - sarcomas: rare
    - most commonly Phyllodes tumour, a variant of fibroadenoma with potential for malignancy
    - can also be angiosarcomas – after previous radiation
  - lymphoma: rare
  - other: papillary, medullary, mucinous, tubular cancers
    - generally better prognosis

BCS = breast-conserving surgery; SLNB = sentinel lymph node biopsy

*If no reason to select mastectomy, the choice between BCS + radiotherapy and mastectomy can be made according to patient’s preference since choice of local treatment does not significantly affect survival if local control is achieved.*
Primary Surgical Treatment
- breast-conserving surgery (BCS): lumpectomy with wide local excision
  - for treatment of stage I and II disease
  - must be combined with radiation for survival equivalent to mastectomy
- contraindications:
  - high risk of local recurrence: extensive malignant-type calcifications on mammogram, multifocal primary tumours, or failure to obtain tumour-free margins after re-excision
  - contraindications to radiation therapy (pregnancy, previous radiation, collagen vascular disease)
  - large tumour size relative to breast
- mastectomy
  - radical mastectomy (rarely done anymore): removes all breast tissue, skin, pectoralis muscle, axillary nodes
  - modified radical mastectomy (MRM): removes all breast tissue, skin, and axillary nodes
  - simple mastectomy: removes all breast tissue and skin
  - see Plastic Surgery, PL32 for breast reconstruction
- axillary lymph node dissection (ALND)
  - performed if SLNB is positive or nodes are clinically concerning
  - risk of arm lymphedema (10-15%), decreased arm sensation, shoulder pain
- sentinel lymph node biopsy (SLNB)
  - technetium-99 ± blue dye injected at tumour site prior to surgery to identify sentinel node(s)
  - intraoperative frozen section
  - proceed with ALND if positive
  - 5% false negative rate

Adjuvant/Neoadjuvant
- radiation
  - indications:
    - decrease risk of local recurrence; almost always used after BCS, sometimes after mastectomy (if >4 nodes positive or tumour >5 cm)
    - inoperable locally advanced cancer
  - axillary nodal radiation may be added if nodal involvement
- hormonal
  - indications:
    - ER positive plus node-positive or high-risk node-negative
    - palliation for metastases
    - tamoxifen if premenopausal or aromatase inhibitors (e.g. anastrozole)
    - ovarian ablation (e.g. goserelin/GnRH agonist, oophorectomy), progestins (e.g. megestrol acetate), androgens (e.g. fluoxymesterone) are other options
- chemotherapy
  - indications:
    - ER negative plus node-positive or high-risk node-negative
    - ER positive and young age
    - stage I disease at high risk of recurrence (high grade, lymphovascular invasion)
    - palliation for metastatic disease

Post-Treatment Follow-up
- visits q3-6mo x 2 yr and annually thereafter (frequency is controversial)
- annual mammography; no other imaging unless clinically indicated
- psychosocial support and counseling

Local/Regional Recurrence
- recurrence in treated breast or ipsilateral axilla
- 1% per year up to maximum of 15% risk of developing contralateral malignancy
- 5x increased risk of developing metastases

Metastasis
- bone > lungs > pleura > liver > brain
- treatment is palliative: hormone therapy, chemotherapy, radiation

Twenty-year Follow-up of a Randomized Study comparing Breast-conserving Surgery with Radical Mastectomy for Early Breast Cancer
*N*EJM 2002;16:1227-1232

**Background:** Women enrolled in a randomized trial to compare the efficacy of radical mastectomy (RM) with that of breast-conserving surgery (BCS) were followed over a 20-yr period for long-term outcomes including disease recurrence and survival.

**Methods:** From 1973-1980, 701 women with breast cancers measuring <2 cm in diameter were randomly assigned to undergo RM (n = 349) or BCS followed by radiotherapy to the ipsilateral breast (n = 352).

**Results:** Rates of ipsilateral disease recurrence were lower in patients treated with RM compared to BCS (crude cumulative incidence 2.3% versus 8.8% after 20 yr; P < 0.001). However, there was no significant difference in rates of contralateral breast malignancies, metastatic spread, or second primary malignancies between the two groups. All-cause mortality rates were 41.7% in the BCS group and 41.2% in the RM group (P = 0.8), with mortality rates due to breast cancer of 26.1% and 24.3% respectively (P = 0.8).

**Conclusion:** The long-term survival rate among patients treated with breast-conserving surgery and adjuvant radiotherapy is the same as that among patients treated with radical mastectomy.

There is no survival benefit of mastectomy over lumpectomy plus radiation for stage I and II disease.
Surgical Endocrinology

Thyroid and Parathyroid

- see Endocrinology, E20 and Otolaryngology, OT34-OT37

Thyroidectomy
- indications: thyroid cancer, symptomatic thyroid mass or goiter, medically refractory Graves' or hyperthyroidism
- contraindications: uncontrolled severe hyperthyroidism (i.e. Graves') due to risk of intraoperative or postoperative thyroid storm
- preoperative workup: thyroid ultrasound for thyroid nodules, fine needle aspiration for large nodules, ultrasound of the neck for lesions suspicious for papillary or medullary thyroid cancer, CT neck useful to rule out extension, vocal cord function
- complications: hypocalcemia secondary to hypoparathyroidism, recurrent/superior laryngeal nerve injury, neck hematoma, infection, thyrotoxic storm

Parathyroidectomy
- indications: symptomatic primary hyperparathyroidism due to effects of PTH on bone or kidneys, asymptomatic primary hyperparathyroidism with specific laboratory criteria (elevated serum Ca, marked hypercalciuria, Cr clearance less than 30% normal, bone density reduction with T score less than 2.5, age less than 50)
- contraindications: familial hypocalciuric hypercalcaemia
- preoperative workup: 99mTc sestamibi scanning, ± SPECT or CT, ultrasound
- complications: recurrent/superior laryngeal nerve injury, postoperative hypocalcemia, infection, bleeding

Adrenal Gland

- see Endocrinology, E29
- functional anatomy:
  - cortex: glomerulosa (mineralocorticoids), fasciculata (glucocorticoids), reticularis (sex steroids)
  - medulla: catecholamines (epinephrine, norepinephrine)
- types: functional (e.g. Cushing's syndrome, Conn's syndrome) or non-functional

INCIDENTALOMA
- adrenal mass discovered by investigation of unrelated symptoms

Epidemiology
- benign adenoma (38%) > metastases to adrenal (22%) >> cyst, carcinoma, pheochromocytoma, neuroblastoma
- metastasis to adrenal gland from: lung > breast, colon, lymphoma, melanoma, kidney
- peak incidence of carcinoma: females age 50-60, risk decreases with increasing age and male gender

Investigations
- MRI, CT: size >6 cm is best predictor of primary adrenal carcinoma (92% are >6 cm)
- functional studies:
  - pheochromocytoma: 24 h urine epinephrine, norepinephrine, metanephrine, normetanephrine, VMA (vanillylmandelic acid)
  - Cushing's: 24 h urine cortisol or 1 mg overnight dexamethasone suppression test
  - aldosteronoma: electrolytes, aldosterone:renin level, saline suppression test if appropriate
  - adrenal androgens: 17-OH progesterone, DHEAS
- FNA biopsy: if suspect metastasis to adrenal (must exclude pheochromocytoma first)
  - indicated if history of cancer or patient is smoker
  - iodocholesterol scintigraphy: may distinguish benign vs. malignant disease

Treatment
- functional tumour: resect
- non-functioning tumour:
  - >4 cm: resect
  - <4 cm: follow-up imaging in 6-12 mo, resect if >1 cm enlargement
Pancreas

INSULINOMA
- Tumour that secretes insulin
- Most common pancreatic endocrine neoplasm; 10% associated with MEN1 syndrome

Clinical Features
- Whipple’s triad
- Palpitations, trembling, diaphoresis, confusion, seizure, personality changes

Investigations
- Bloodwork: decreased serum glucose and increased serum insulin and C-peptide
- U/S, CT: Insulinomas evenly distributed throughout head, body, tail of pancreas

Treatment
- Only 10% are malignant
- Enucleation of solitary insulinomas may be done endoscopically
- Tumours >2 cm located close to the pancreatic duct may require pancreatectomy or pancreaticoduodenectomy

GASTRINOMA
- Tumour secreting gastrin; cause of Zollinger-Ellison syndrome

Clinical Features
- Abdominal pain, peptic ulcer disease, severe esophagitis
- Multiple ulcers in atypical locations refractory to antacid therapy

Investigations
- Bloodwork: serum gastrin levels (usually >1000 pg/mL), secretin stimulation test
- U/S, CT: 70-90% found in Passaro’s triangle (head of pancreas, duodenum, lymphatic bed posterior and superior to the duodenum)
- Octreotide scintigraphy scan

Treatment
- 50% are malignant
- Surgical resection of tumour dependent on location
- Non-surgical treatment: chemotherapy, somatostatin analogues, interferon, chemoembolization
- If inoperable vagotomy can be performed for symptomatic control

VASOACTIVE INTESTINAL PEPTIDE-SECRETING TUMOUR
- Tumour secreting vasoactive intestinal peptide (VIP); commonly located in the distal pancreas and most are malignant when diagnosed

Clinical Features
- Severe watery diarrhea causing dehydration, weakness, electrolyte imbalance

Investigations
- Bloodwork: serum VIP levels
- U/S, CT

Treatment
- Somatostatin analogues
- Surgical resection/palliative debulking

**Malrotation**

1/500 live births 1/3 present by 1 wk of age, 3/4 by 1 mo of age, 80% by 1 yr of age M:F = 1:1; higher incidence among patients with cardiac anomalies, heterotaxy syndromes Failure of gut to normally rotate around superior mesenteric artery with associated abnormal intestinal attachments and anatomic positions Represent a spectrum of rotational abnormalities including complete non-rotation (which is not at high risk for volvulus) Bilious emesis is THE cardinal sign, especially if abdomen nondistended. If bilious emesis in ill child with distended abdomen, consider surgical exploration to rule out volvulus. Racial bleed (late/ominous signs) Intermittent symptoms Bilious drainage from NG tube Tachycardic, pale Diaphoretic Flat abdomen Tenderness AXR: obstruction of proximal small bowel, double-bubble sign, intestinal wall thickened Immediate UGI. Dilated duodenum, duodenojejunal segment (Ligament of Treitz) right of midline and not fixed posteriorly over spinal column, “corkscrew” sign indicating volvulus U/S: “whirlpool” sign, abnormal SMA/SMV relationship indicates UGI to rule out rotational anomalies IV antibiotics Fluid resuscitation EMERGENT LAPAROTOMY Ladd procedure: counter-clockwise reduction of midgut volvulus, division of Ladd’s bands, division of peritoneal attachments between cecum and abdominal wall that obstruct duodenum, broadening of the mesentery (open folded mesentery i.e. a book and divide congenital adhesions), ± appendectomy Positioning the bowel into non-rotation (small bowel in right abdomen, large bowel in left abdomen) Mortality related to length of bowel volvulus: 10% necrosis – 100% survival rate, 75% necrosis – 25% survival rate Recurrence 2-6%

**Gastrochisis**

1:2000 live births Antenatal diagnosis common Increases with younger maternal age and associated with IUGR M:F = 1:1 Defect of abdominal wall, with free extrusion of intestine into amniotic cavity No specific environmental factor identified Defect in embryogenesis unclear Not associated with genetic syndromes 10% with intestinal atresia Some cases associated with short bowel syndrome due to antenatal volvulus and necrosis of herniated bowel Hollow viscera (stomach, small and large bowels) Defect lateral to cord (usually right) Bowel may be inflamed, thickened, matted, foreshortened Defect size variable Hollow viscera (stomach, small and large bowels, often liver) Cord on the sac Prenatal ultrasound, elevated MS-AFP NG decompression IV fluids IV antibiotics Keep viscera moist and protected until surgical reduction with primary abdominal closure or staged closure with site May have bowel dysmotility requiring motility medications >90% survival rate

**Omphalocele**

1:5000 live birth Antenatal diagnosis common Lower gestational age Increased maternal age M:F = 1.5:1 Defect of abdominal wall, with extrusion of sac covered viscera (amnion, Wharton’s jelly, peritoneum) Duhameel’s theory – failure of body wall morphogenesis Associated with genetic syndromes 30-70% (e.g. Pentalogy of Cantrell, congenital heart disease, Beckwith-Wiedemann syndrome) Associated pulmonary hypoplasia Hollow viscera (stomach, small and large bowels, often liver) Cord on the sac Prenatal ultrasound Elevated MS-AFP NG decompression IV fluids IV antibiotics Small defect (<2 cm): Primary closure Medium (2-4 cm) and large (>4 cm) defects best treated with silver sulfadiazine to promote epithelialization coupled with compression dressing to allow gradual reduction, followed by future repair with or without mesh 40-70% survival rate Higher survival rates most likely related to antenatal mortality of fetuses with giant omphaloceles

---

Bilious vomiting in infant is a life-threatening emergency secondary to midgut volvulus until proven otherwise.

**Rule of 2s for Meckel’s Diverticulum**
- 2% of the population
- 2:1 male-to-female ratio
- Symptomatic in 2% of cases
- Found within 2 feet (10-90 cm) of the ileocecal (IC) valve
- 2 inches in length
- 2 inches in diameter
- 2 types of tissue (gastric, pancreatic)
- Often present by 2 yr of age

<tr>
<td><strong>Umbilical Hernias</strong></td>
<td>Incidence 2-14% Increases with prematurity Decreases with increasing age</td>
<td>Incapable closure of peritoneal and fascial layers within umbilicus by 5 yr</td>
<td>Majority asymptomatic Majority spontaneously resolve by age 5 Incarceration prior to age 5 very rare Most symptoms occur in late adolescence or adulthood</td>
<td>Protrusion from umbilicus Important to differentiate from less common abdominal wall hernias that don’t spontaneously resolve (e.g. epigastric hernias) Most umbilical fascial defects &gt; 1.5 cm in infancy will not close spontaneously</td>
<td>None if uncomplicated Repair if not spontaneously closed by age 5 Earlier repair of large “proboscoid” hernias with extensive skin stretching may be warranted for cosmetic reasons Simple primary closure of fascial defect</td>
<td>Low risk of recurrence</td>
<td></td>
</tr>
</tbody>
</table>
| **Intestinal Atresia** | Incidence 2-14% May be antenatally diagnosed by dilated bowel loops or “double-bubble” sign on x-ray for duodenal atresia Decreasing with increasing age                                                                                      | Duodenal – failure of bowel to recanalize after endodermal epithelium proliferation (wk 8-10) Jejunal/ileal – acquired as result of vascular disruption  
isoamnic necrosis  
resorption of necrotic tissue  
blind distal and proximal ends Colon – mechanism unknown, thought to be similar to small bowel atresia | Gastric distension and vomiting (usually bilious) Duodenal – may be associated with other anomalies  
(tracheoesophageal fistula, cardiac, renal and vertebral anomalies), 24-28% have Down syndrome Jejunal/ileal – within 2 d of birth, may be associated with cystic fibrosis Colonic – within 3 d of birth | Complete physical Special notice to abdominal exam Perineum and anus Include evaluation of respiratory distress and signs of volume depletion Congenital anomalies Jaundice | Contrast enema ± USI with small bowel follow through (SBFT) Group and screen INR and PTT if for surgery | NPO NG tube decompression Fluid resuscitate TPN Broad spectrum antibiotics Duodenal – duodenoduodenostomy or duodenojejunostomy Jejunal/ileal – primary anastomosis; or if atresia associated with short bowel then may create end stoma or defer surgery for bowel lengthening procedures Colonic – primary anastomosis | Long term survival Duodenal – 86% Jejunal/ileal – 84% Colonic – 100% |
| **Hirschsprung’s Disease** | 1:5000 births M:F = 3:1-4:1, approaches 1:1 when whole colon involved Can have aganglionosis of small bowel as well Familial Hirschsprung’s in < 5% of cases                                                                 | Defect in migration of neurocrest cells to intestine resulting in aganglionic bowel that fails to peristate and internal sphincter that fails to relax (internal anal sphincter achalasia) causing functional and partial mechanical obstruction, respectively always starts in the rectum and variable involvement proximally; RET mutation | Failure to pass meconium spontaneously within 48 h of life is the classic history (95% of normal children should pass meconium within 24 h, and the remaining 5% within 46 h) Symptoms of bowel obstruction: 
abdominal distension, constipation, bilious emesis Enterocolitis/sepsis Failure to thrive | ± abdominal distension Squat/burst sign Rectal biopsy (gold standard) – look for aganglionosis and neural hypertrophy AXR Contrast enema to find narrow rectum and transition zone Anal manometry unreliable in infants – classic finding is absence of rectoanal inhibitory reflex | Surgical resection of aganglionic intestinal segment and anastomosis of remaining intestine to anus Either in newborn period or staged if extensive aganglionosis | Most have normal/ near-normal anorectal function Complications: Fecal incontinence and constipation, post-operative enterocolitis (medical emergency if progresses to sepsis) |
| **Cryptorchidism**   | 2-5% of term males – most of these descend spontaneously by 6 mo of age 1% of males do not spontaneously descend                                                                                                                                 | Idiopathic Descent is mediated by descendin which is created in response to testosterone Descent usually begins at 28 wk | Palpable testicle within inguinal canal or testicle which can be milked down into scrotum (called retractile testis) Occasionally no palpable testis as it is intra-abdominal Consider other congenital abnormalities | Bi-annual testicular exam with palpation Distinguish truly undescended testis from retractile testis (which is “high” testes due to hypertrophic cremasteric muscles) | Depends on age of presentation U/S or MRI exam if no palpable testis Older child: LH, FSH, MIS, hCG stimulation test for gonadotropin production Infant: U/S, FSH, LH, karyotyping, MIS, 17-Hydroxyprogesterone | InCG to stimulate testosterone production and desent Orchidopexy – especially if descended by age 6 mo-2 yr | Orchidopexy Decreased risk of torsion and blunt trauma to testicle No effect on malignant potential of testicle Descent can preserve spermatogenesis if performed by 1 yr of age 1/1000 risk for testicular cancer (population risk is 1/4000) |
### Table 22. Pediatric Surgery (continued)

<table>
<thead>
<tr>
<th>Condition</th>
<th>Epidemiology and Risk Factors</th>
<th>Pathophysiology</th>
<th>Clinical Features and History</th>
<th>Physical Features</th>
<th>Investigations</th>
<th>Treatment</th>
<th>Prognosis</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Intussusception</strong></td>
<td>Most common cause of bowel obstruction between the ages of 6-36 mo. 26/100,000 newborns. More common in males (3:2). Pathologic lead points: enlarged Peyer’s patches due to viral infections.</td>
<td>Idiopathic is most common. Usually starts at ileocecal junction. Telescoping of bowel into itself causing an obstruction and vascular compromise.</td>
<td>Acute onset of abdominal pain which is classic episodic. &quot;colicky&quot; pain. Vomiting of bile or bilious stool. Abdominal mass. Current-jelly stool suggests mucosal necrosis and sloughing.</td>
<td>Abdominal exam</td>
<td>X-ray</td>
<td>If peritonitis, then consider operative management. Non-operative management involves reduction via air contrast enema. Operative reduction can be done open or laparoscopically. Resection of involved colon if failure to reduce or bowel appears compromised.</td>
<td>10% recurrence rate. If recurrent = more likely non-idiopathic. In successfully reduced by enema in older children allow 2 wk resolution of edema then perform SBFT to rule out pathologic lead points.</td>
</tr>
<tr>
<td><strong>Tracheoesophageal Fistula (TEF)</strong></td>
<td>Associated anomalies in 50%: VACTERL association (see Pediatrics. P41).</td>
<td>Varies with type of fistula. May have history of maternal polyhydramnios. May present after several months (if no associated esophageal atresia) of non-bilious vomiting, coughing, cyanosis of mass may be noted.</td>
<td>X-ray: anatomic abnormalities, NG tube curled in pouch.</td>
<td>Investigate for other congenital anomalies, early repair by surgical ligation to prevent lung damage and maintain nutrition and growth.</td>
<td>Complications: pneumonia, sepsis, reactive airways disease. Following repair: esophageal stenosis and strictures at repair site, gastroesophageal reflux and poor swallowing (i.e. dysphagia, regurgitation).</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Inguinal Hernias</strong></td>
<td>5% of all term newborns. 2x risk and more likely bilateral if pre-term. More common in males (4:1). Low birth weight increases risk. 1/5 inguinal hernias will become incarcerated if patient is &lt; 1 yr old. Incarceration is more common in females. Associated with other conditions: androgen insensitivity, connective tissue diseases.</td>
<td>All infant hernias are indirect. Descent of the internal inguinal ring through the patent inguinal canal.</td>
<td>Physical exam is gold standard. U/S only if physical exam uncertain (e.g. polyhydramnios).</td>
<td>Manual reduction – to relieve acute symptoms. Herniorraphy – definitive treatment by reduction of herniated contents and high ligation of sac for indirect hernias.</td>
<td>10% recurrence rate. If recurrent = more likely non-idiopathic. In successfully reduced by enema in older children allow 2 wk resolution of edema then perform SBFT to rule out pathologic lead points.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Skin Lesions

- see Dermatology, D5; Emergency, ER17; Plastic Surgery, PL5

All inguinal hernias of infancy and childhood require repair at the earliest convenience. Emergent repair if incarcerated/strangulated!
Common Medications

Antimicrobials
- dimenhydrinate (Gravol®) 25-50 mg PO/IV/IM q4-6h pm
- prochlorperazine (Stemetil®) 5-10 mg PO/IV/IM bid-tid pm
- metoclopramide (Maxeran®) 10 mg IV/IM q2-3h pm, 10-15 mg PO qid (30 min before meals and qhs)
- ondansetron (Zofran®) 4-8 mg PO qd pm
- granisetron (Kytril®) 1 mg PO bid (for nausea from chemotherapy/radiation)

Analgesics
- acetaminophen ± codeine (Tylenol® #3,plain) 1-2 tabs q4-6h PO/PR pm
- morphine 2.5-10 mg IM/SC q 4-6h pm + 1-2 mg IV q1h pm for breakthrough
- ketorolac (Toradol®) 30-60 mg IM/IV q6h pm
- Percocet® (acetaminophen/oxycodeine, 325/5 mg) 1-2 tabs PO q4-6h pm

DVT Prophylaxis
- heparin 5000 units SC bid, if cancer patient then heparin 5000 units SC tid
- dalteparin (Fragmin®) 5000 units SC daily
- enoxaparin (Lovenox®) 40 mg SC daily

Antidiarrheals
- loperamide (Imodium®) 4 mg PO initially, then 2 mg PO after each loose stool up to 16 mg/d
- diphenoxylate + atropine (Lomotil®) 2 tabs/10 mL PO qid

Laxatives
- sennosides (Senokot®) 1-2 tabs qhs
- docusate sodium (Colace®) 100 mg PO bid
- glycerine suppository 1 tab PR pm
- lactulose 15-30 mL PO qid pm
- milk of magnesia (MOM) 30-60 mL PO qid pm
- bisacodyl (Dulcolax®) 10-15 mg PO pm

Sedatives
- zopiclone (Imovane®) 5-7.5 mg PO qhs pm
- lorazepam (Ativan®) 0.5-2 mg PO/SL qhs pm

Antibiotics
- cefazolin (Ancef®) 1 g IV/IM on call to OR or q8h – GP except Enterococcus, GN only
- cefalexin (Keflex®) 250-500 mg PO qid – Listeria, GP except Enterococcus, GN only
- ceftriaxone 1-2 g IM/IV q24h – broad covering including Pseudomonas
- ampicillin 1-2 g IV q4-6h – Listeria, GP (Enterococcus) except Streptococcus and E. coli, oral anaerobes except Bacteroides
- gentamicin 3-5 mg/kg IM/IV divided q8h; monitor creatinine, gentamicin levels – GN including Pseudomonas
- ciprofloxacin 400 mg IV q12h, 500 mg PO bid – GN including Pseudomonas
- metronidazole (Flagyl®) 500 mg PO/IV bid, (500 mg PO tid for C. difficile) – anaerobes
- clindamycin 600-900 mg IV q8h, 150-400 mg PO qid – GP except Enterococcus, anaerobes

Over-the-Counter Medications
- Pepcid-Bismol® (bismuth subsalicylate) 2 tabs or 30 mL PO q30min-1h up to 8 doses/d
- Pepto-Bismol® (aluminum hydroxide and magnesium hydroxide) 2 tabs or 30 mL PO q30min-1h up to 8 doses/d
- Alka-Seltzer® (ASA + citrate + bicarbonate) 2 tabs in 4 oz water PO q4h pm, max 8 tabs
- Maalox® (aluminum hydroxide + magnesium hydroxide) 10-20 mL or 1-4 tabs PO pm
- Tums® (calcium carbonate) 1-3 g PO q2h pm
- Rolaid® (calcium carbonate and magnesium hydroxide) 2-4 tabs PO q1h pm, max 12 tabs/d

Physiology and Pathology of Aging

Definition

- major categories of impairment that appear with old age and affect the physical, mental and social domains of the elderly, usually due to many predisposing and precipitating factors, rather than a single cause

Table 2. Changes Occurring Frequently with Aging

<table>
<thead>
<tr>
<th>System</th>

</table>
**Differential Diagnoses of Common Presentations**

**Constipation**
- see *Gastroenterology*, G24

**Definition**
- less than 3 bowel movements in one week and/or hard stools, straining, sense of blockage, needing manual maneuvers or incomplete evacuation on more than 25% of occasions for at least 12 wk (does not need to be consecutive)

**Epidemiology**
- chronic constipation increases with age (up to 1/3 of patients >65 yr experience constipation)

**Pathophysiology**
- impaired rectal sensation (increased rectal distention required to stimulate the urge to defecate)
- colorectal dysmotility

**Treatment**
- non-pharmacological
  - increase fibre intake
  - ensure adequate fluid intake
  - discourage chronic laxative use
  - engage in regular exercise
  - review medication regime, reduce dosages or substitute
- pharmacologic
  - see *Common Medications*, GM15

**Risk Factors for Constipation in the Elderly**
- Immobility
- Diet: low fibre/calorie diet, dehydration
- Medications:
  - Polypharmacy
  - Drugs: narcotics, calcium channel blockers, anticholinergics
- GI: obstructive lesions (bowel obstruction, cancer, diverticular disease, IBD, strictures, uterine prolapse), altered colonic motility (IBS, colonic inertia)
- Neurological: spinal cord injury, Parkinson’s disease, stroke, autonomic dysfunction
- Metabolic: diabetes, hypokalemia, hypercalcemia
- Psychiatric: depression, dementia

**Figure 1. Treatment algorithm for the management of chronic constipation in the elderly**
Adapted from: Clin Interv Aging 2010;5:163-171

**Delirium, Dementia and Depression**
- see *Psychiatry*, PS19, PS20, PS9 and *Neurology*, N17

**Definition**
- pathologic decrease in memory, language, or executive function

**Differential Diagnosis**
- delirium, dementia, or pseudodementia of depression

</tbody>
</table>

Delirium Prevention in Elderly
- ensure optimal vision and hearing to support orientation (e.g. clean, appropriate eyewear and hearing aids)
- provide adequate nutrition and hydration (up in chair to eat and drink whenever feasible)
- encourage regular mobilization to build and maintain strength, balance and endurance
- avoid unnecessary medications and monitor for drug interactions
- avoid bladder catheterization if possible
- ensure adequate sleep

Elder Abuse

Definition
- includes physical abuse, sexual abuse, emotional/psychological abuse, financial abuse, abandonment and neglect
- elder abuse is a criminal offence under the Criminal Code of Canada
- in the U.S., most states have criminal penalties for elder abuse

Epidemiology
- in Canada, approximately 4% of elderly persons living in private homes have suffered abuse
- in the U.S., estimates of the frequency of elder abuse range from 3-8%
- physician reporting is mandatory only in Newfoundland, Nova Scotia and Prince Edward Island; in Ontario, only abuse occurring in nursing homes is mandatory to report
- insufficient evidence to include/exclude screening in the Periodic Health Exam

Risk Factors

Table 4. Risk Factors for Elder Abuse

<table>

Caregiver Abuse Screen (CASE)

- **Instructions:**
  1. Answer “yes” to any of the following questions.
  2. Ask the person if the abuse is occurring.
  3. Do not answer “yes” to any of the following questions.
  4. Ask the person if the abuse is occurring.

- **Screening Tool:**
  1. Do you often feel you are being forced to act out of character or do things you feel badly about?
  2. Do you often feel you are being forced to act out of character or do things you feel badly about?
  3. Do you often feel you are being forced to act out of character or do things you feel badly about?
  4. Do you often feel you are being forced to act out of character or do things you feel badly about?
  5. Do you often feel you are being forced to act out of character or do things you feel badly about?
  6. Do you often feel you are being forced to act out of character or do things you feel badly about?
  7. Do you often feel you are being forced to act out of character or do things you feel badly about?

From: NICE. Case: Caregiver Abuse Screen. 2010. Reproduced with permission from NICE.

Management

- Assess safety and determine capacity to make decisions about living arrangements.
- Establish need for hospitalization or alternative accommodation (e.g., immediate risk of physical harm by self or caregiver).
- Involve multidisciplinary team (e.g., nurse, social worker, family members and physicians, including geriatrician, psychiatrist or family physician).
- Educate and assist caregiver, contact local resources (e.g., legal aid, crisis support, PSW, caregiver support groups).
- Interpret critical and lab findings that are key in exclusion, differentiation and diagnosis.

Falls

**Epidemiology**

- 30-40% of people >65 yr old and ~50% of people >80 yr old fall each year.
- Equally common between men and women, but more likely to result in injury in women.
- 5% of falls lead to hospitalization.
- 5-10% associated with serious injuries (e.g., hip fracture, head injury, laceration).
- 1-2% of falls associated with hip fracture.
- 15% die in hospital, 33% 1-yr mortality.
- Between 25-75% do not recover to previous level of ADL function.
- Mortality increases with age (171/100,000 in men >85 yr old) and type of injury (25% with hip fracture die within 6 mo).

**Etiology**

- Multifactorial.
- Extrinsic:
  - Environmental (e.g., home layout, lighting, stairs, footwear), accidental, abuse.
  - Medications/substances (e.g., alcohol).
- Intrinsic:
  - Orthostatic/syncopal.
  - Age-related changes and diseases associated with aging: musculoskeletal (arthritis, muscle weakness), sensory (visual, proprioceptive, vestibular), cognitive (depression, dementia, delirium, anxiety), cardiovascular (CAD, arrhythmia, MI, low BP), neurologic (stroke, decreased LOC, gait disturbances/ataxia), metabolic (glucose, electrolytes).
- Past history of a fall.

**Investigations**

- Directed by history and physical.
- Comprehensive geriatric assessment to identify all potential causes.
- CBC, electrolytes, BUN, creatinine, glucose, Ca++, TSH, B12, urinalysis, cardiac enzymes, ECG, CT head.

**Prevention**

- Multidisciplinary, multifactorial, health and environment risk factor screening and intervention programs in the community.
- Muscle strengthening, balance retraining and group exercise programs (e.g., tai chi).
- Home hazard assessment and modification (e.g., remove rugs, add shower bars, etc.).
- Prescription of vitamin D 1000 IU daily.
- Tapering or gradually discontinuation of psychotropic medication.
- Postural hypotension, heart rate, and rhythm abnormalities management.
- Eyesight and footwear optimization.

FECAL INCONTINENCE

Epidemiology
- second leading cause of nursing home placement

Etiology
- commonly multifactorial
  - structural abnormalities
  - trauma (e.g. prior vaginal delivery, surgery)
  - prolapse
  - tumour/trauma (e.g. brain, spinal cord, cauda equina)
  - overflow (e.g. encopresis, impaction)
- functional abnormalities
  - neurologic conditions – neuropathy, multiple sclerosis, stroke, dementia
- others
  - constipation with overflow may be a factor
  - psychosis (willful soiling)
  - age >80 yr: decreased external sphincter strength and weak anal squeeze, increased rectal compliance, decreased resting tone and internal sphincter, impaired anal sensation
  - medications (e.g. laxatives, anticholinergics, antidepressants, caffeine, muscle relaxants)

Investigations (if cause not apparent from history and physical)
- differentiate true incontinence from frequency and urgency (i.e. IBS, IBD)
- stool studies
- endorectal ultrasound
- colonoscopy, sigmoidoscopy, anoscopy
- anorectal manometry/functional testing

Management
- diet/bulking agent if stool is liquid or loose
- disimpaction, prevent impaction
- anti-diarrheal agents (e.g. loperamide)
- regular defecation program in patients with dementia
- counsel about biofeedback therapy (retraining of pelvic floor muscles)
URINARY INCONTINENCE

- see Urology, U6

Epidemiology

- 15-30% prevalence dwelling in community and at least 50% of institutionalized seniors
- morbidity: cellulitis, pressure ulcers, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction
- not associated with increased mortality

Pathophysiology

- not a normal part of aging, urinary incontinence is a loss of control due to a combination of:
  - genitourinary pathology: increased post-void residual volume, increased involuntary bladder contractions (urge incontinence)
  - age-related changes: decreased bladder capacity
  - comorbid conditions and medications
  - functional impairment
- in elderly women: decline in bladder outlet and urethral resistance pressure promoting stress incontinence
- in elderly men: prostatic enlargement can cause overflow and urge incontinence

## Gait Disorders

- see Neurology, N29

## Hazards of Hospitalization

## Hypertension

- see Family Medicine, FM37

- 60-80% of elderly (>65 yr old) have hypertension
- 60% of these have isolated systolic HTN
- the benefit of treating hypertension in the elderly is 2-4 times greater than that achieved in the treatment of younger patients with primary hypertension
- systolic and pulse pressure are major predictors of outcome in the elderly patient
- in older adults, base treatment on sBP
- target BP: sBP <140, 65<dBP<90; for patients with DM: sBP <130, dBP <80
- not recommended to lower BP below 120/80
- treatment:
  - non-pharmacologic treatments are first-line, then thiazide monotherapy is recommended
  - add ACEI/ARB if also atherosclerosis, DM, CHF or chronic kidney disease
  - add β-blockers if also angina or CHF

## Treatment of Hypertension in Patients 80 Years of Age or Older

**NEJM 2008;358:1887-1898**

- Study: Randomized, double-blind, placebo-controlled, multicentre trial.
- Subjects: 3845 patients who were 80 yr of age or older and had a sustained systolic blood pressure of 160 mmHg were followed for a median 1.8 yr.
- Intervention: Indapamide (sustained release, 1.5 mg) or matching placebo. The angiotensin-converting enzyme inhibitor perindopril (2 or 4 mg), or matching placebo, was added if necessary to achieve the target blood pressure of 150/90 mmHg.
- Primary Outcome: Fatal or nonfatal stroke.
- Results: Mean BP was 173.0/90.8 mmHg. At 2 yr, the mean BP while sitting was 151.0/71.1 mmHg lower in the treatment group than in the placebo group. Treatment was associated with a 30% reduction in the rate of fatal or nonfatal stroke (95% CI, –1 to 81; p=0.00), 39% reduction in the rate of death from stroke (95% CI, 1 to 82; p=0.05), 21% reduction in the rate of death from any cause (95% CI, 4 to 35; p=0.02), 23% reduction in the rate of death from cardiovascular causes (95% CI, –1 to 40; p=0.08), and 64% reduction in the rate of heart failure (95% CI, 42 to 78; p<0.001). Fewer serious adverse events were reported in the treatment group (356 vs. 448 in the placebo group; p=0.001).
- Conclusions: Antihypertensive treatment with indapamide (sustained release, with or without perindopril), in persons 80 yr of age or older reduces death from stroke, death from any cause and the incidence of heart failure.
**Immobility**

**Complications**
- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- musculoskeletal: atrophy, contractures, bone loss
- skin: pressure ulcers
- psychological: sensory deprivation, delirium, depression

**Immunizations**
- the following immunizations are recommended for people 65 yr of age and older
  - tetanus: every 10 yr
  - pneumococcus: every 5 yr
  - influenza: every autumn
  - herpes zoster: Zostivax®

**Malnutrition**

**Definition**
- involuntary weight loss of ≥5% baseline body weight or ≥5 kg
- hypoalbuminemia, hypocholesterolemia

**Etiology**
- nutritional
  - decreased assimilation: impaired transit, maldigestion, malabsorption
  - decreased intake: financial, psychiatric (depression), cognitive deficits, anorexia associated with chronic disease, functional deficits (e.g. difficulty shopping, preparing meals or feeding oneself due to functional impairment)
- stress: acute or chronic illness/infection, chronic inflammation, abdominal pain
- mechanical: dental problems, dysphagia
- age-related changes: appetite dysregulation, decreased thirst
- mixed: increased energy demands (e.g. hyperthyroidism), abnormal metabolism, protein-losing enteropathy

**Clinical Features**
- history
  - recent or chronic illness
    - depression, GI symptoms
  - functional disability: impaired ADLs and IADLs
  - social factors: economic barriers, dental problems and living situation (e.g. living alone)
  - constitutional symptoms e.g. recent weight loss
- physical examination
  - BMI <23.5 in males, <22 in females should raise concern
  - temporal wasting, muscle wasting, presence of triceps skin fold
  - assess cognition

**Investigations**
- CBC, electrolytes, Ca²⁺, Mg²⁺, PO₄⁻³, creatinine, LFTs (albumin, INR, bilirubin), B₁₂, folate, TSH, transferrin, lipid profile, urinalysis, ESR, CXR

**Osteoporosis**
- see Endocrinology, E42

**Presbycusis**
- see Otolaryngology, OT19
Pressure Ulcers

• see Plastic Surgery, PL16

Risk Factors
• extrinsic factors: friction, pressure, shear force
• intrinsic factors: immobility, malnutrition, moisture, sensory loss

Table 7. Classification of Pressure Ulcers

| Stage I | Changes include skin temperature, tissue consistency or sensation |
| Stage II | Partial thickness skin loss involving the epidermis, dermis or both |
| Stage III | Full thickness skin loss involving damage or necrosis of subcutaneous tissue which may extend down to, but not through, underlying fascia |
| Stage IV | Full thickness skin loss with extensive destruction, tissue necrosis or damage to muscle, bone or supporting structures |

Prevention
• pressure reduction
  • frequent repositioning
  • pressure-reducing devices (static, dynamic)
• maintaining nutrition, encouraging mobility and managing incontinence

Treatment
• optimize nutritional status
• minimize pressure on wound
• analgesia
• wound debridement (mechanical, enzymatic, autolytic) and dressing application
• maintain moist wound environment to enable re-epithelialization
• treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)
• swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
• stage IV ulcers typically warrant surgical debridement
• consider other treatment options
  • negative pressure wound therapy/vacuum-assisted closure (VAC)
  • biological agents: application of fibroblast growth factor, platelet-derived growth factor to wound
  • non-contact normothermic wound therapy
  • electrotherapy

Driving Competency

Reporting Requirements
• physician-reporting to the Ministry of Transportation is mandatory in all provinces and territories except in Quebec, Nova Scotia and Alberta, where it is discretionary
• not an issue unique to geriatrics – any patient may suffer from a medical condition that impairs their ability to drive should be reported
• in the U.S., varies by state

Conditions that may Impair Driving

Table 8. Conditions that Impair Driving

| Alcohol | Patients with history of impaired driving and those with high probability of future impaired driving should not drive until further assessed |
| Alcohol | Alcohol dependence or abuse: if suspected, should be advised not to drive |
| Alcohol | Alcohol withdrawal seizure: must complete a rehabilitation program and remain abstinent and seizure-free for 6 mo before driving |
| Blood Pressure Abnormalities | Hypertension: sustained BP >170/110 should be evaluated carefully |
| Blood Pressure Abnormalities | Hypotension: if syncopal, discontinue until attacks are treated and preventable |
### Table 8. Conditions that Impair Driving (continued)

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Impairment/Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cardiovascular Disease</td>
<td>Suspected asymptomatic CAD or stable angina: no restrictions</td>
</tr>
<tr>
<td>Cerebrovascular Disease</td>
<td>TIA: should not be allowed to drive until a medical assessment is completed</td>
</tr>
<tr>
<td>Cognitive Impairment/Dementia</td>
<td>Moderate to severe dementia is a contraindication to driving; defined as the &quot;inability to independently perform 2 or more IADLs or any basic ADL&quot;</td>
</tr>
<tr>
<td>Diabetes</td>
<td>Diet controlled or oral hypoglycemic agent: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular or cerebrovascular disease)</td>
</tr>
<tr>
<td>Drugs</td>
<td>Be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants</td>
</tr>
<tr>
<td>Hearing Loss</td>
<td>Effect of impaired hearing on ability to drive safely is controversial</td>
</tr>
<tr>
<td>Musculoskeletal Disorders</td>
<td>If treated appropriately: contraindicated to drive if &lt;120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously</td>
</tr>
<tr>
<td>Seizures</td>
<td>First, single, unprovoked: no driving for 3 mo until complete neurologic assessment, EEG, CT head</td>
</tr>
<tr>
<td>Sleep Disorders</td>
<td>If patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive</td>
</tr>
<tr>
<td>Visual Impairment</td>
<td>Visual acuity: contraindicated to drive if &lt;20/50 with both eyes examined simultaneously</td>
</tr>
</tbody>
</table>

N.B: guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving

### Table 9. Classification of Health Care Services and Institutions

<table>
<thead>
<tr>
<th>Institution/Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Community Support Services</td>
<td>Health care services offered at home for those who can live independently at home or under the care of family members including professional health care services, personal care and support (IADL assistance), homemaking (IADL assistance), community support services (e.g. transportation, meal delivery, day programs, caregiver relief, security checks, etc.)</td>
</tr>
<tr>
<td>Residential</td>
<td>Divided into short (&lt;60-90 d/yr) and long (indefinite) stay</td>
</tr>
<tr>
<td>a) Seniors Affordable Housing</td>
<td>Seniors who live independently and manage their own care but prefer to live near other seniors; usually has accessibility features and rent is adjusted based on income</td>
</tr>
<tr>
<td>b) Retirement/Nursing Home</td>
<td>Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned</td>
</tr>
<tr>
<td>c) Supportive Housing</td>
<td>Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment and may offer some physiotherapy and rehabilitation services</td>
</tr>
<tr>
<td>d) Long-term Care/Skilled Nursing Facility</td>
<td>Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy and rehabilitation services; may be used short-term for caregiver respite or for supportive patient care to regain strength and confidence after leaving the hospital</td>
</tr>
<tr>
<td>e) Hospice</td>
<td>Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis ≤3 mo</td>
</tr>
</tbody>
</table>
Palliative and End-of-Life Care

Principles and Quality of Life

- support, educate and treat both patient and family
- address physical, psychological, social and spiritual needs
- focus on symptom management and comfort measures
- offer therapeutic environment and bereavement support
- ensure maintenance of human dignity

End-of-Life Care Discussions

When to Initiate End-of-Life Care Discussions

- recent hospitalization for serious illness
- severe progressive medical condition(s)
- death expected within 6-12 mo
- patient inquires about end-of-life care

Suggested Topics for Discussion

- goals of care (disease vs. symptom management)
- advance directives, power of attorney, public guardian and trustee
- treatment options and likelihood of success
- common medical interventions
  - mechanical ventilation
  - antibiotic therapy
  - feeding tubes
- resuscitation options and likelihood of success (Full Code vs. DNR status including preferences for CPR, intubation, ICU admission, artificial hydration)

Power of Attorney

- see Ethical, Legal and Organizational Aspects of Medicine, ELOAM8

Instructional Advance Directives

- see Ethical, Legal and Organizational Aspects of Medicine, ELOAM8

Symptom Management

Assessment Tools

- Edmonton Symptom Assessment System (ESAS): a tool that asks patients to rate the intensity of symptoms from 0 to 10 and and allows for tracking of the efficacy of interventions. Assesses: pain, tiredness, nausea, depression, anxiety, drowsiness, appetite, well being, shortness of breath, and "other problem"
- Palliative Performance Scale (PPS): a tool that uses functional status to predict survival in terminally ill patients. Assesses 5 components: ambulation, activity and evidence of disease, self-care, intake and conscious level

Source: Journal of Palliative Care, 1991;7:6-9 and Palliative Performance Scale, Victoria Hospice Society, 2006;120-121
Table 10. Management of Common End-of-Life Symptoms

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Non-Pharmacologic Management</th>
<th>Pharmacologic Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constipation</td>
<td>Rule out obstruction, impaction, anorectal disease; hydration and high fibre intake; increase mobility</td>
<td>Stop unnecessary opioids and medications with anticholinergic side effects; provide stool softern (e.g. docusate sodium), increase peristalsis (e.g. senna), after water and electrolyte secretion (e.g. magnesium hydroxide)</td>
</tr>
<tr>
<td>Death Rattle/Increased Pulmonary Secretions</td>
<td>Oral suctioning</td>
<td>Scopolamine SC or transdermal</td>
</tr>
<tr>
<td>Dry mouth</td>
<td>Oral hygiene q2h, ice cubes, sugarless gum</td>
<td>Artificial saliva substitutes, bethanechol, plicarpine 1% solution as mouth rinse</td>
</tr>
<tr>
<td>Dysphagia</td>
<td>Frequent small feeds, ideally seated, keep head of bed elevated for 30 min after eating, suction as necessary</td>
<td>Treat painful mucositis (diphenhydramine: lidocaine: Maalox® in a 1:2:8 mixture), candiissias (flunonazole)</td>
</tr>
<tr>
<td>Dyspnea</td>
<td>Elevate head of bed, eliminate allergens, open window/use fan</td>
<td>Oxygen, bronchodilators, opioids (e.g. morphine, hydromorphone)</td>
</tr>
<tr>
<td>Hiccups</td>
<td>Dry sugar, breathing in paper bag</td>
<td>Chlorpromazine, haloperidol, metoclopramide, bacoslen, marijuana</td>
</tr>
<tr>
<td>Nausea and Vomiting</td>
<td>Frequent and small meals, avoid offensive strong odours, treat constipation if present</td>
<td>Raised ICP: dexamethasone Anticipatory nausea, anxiety: lorazepam Vestibular disease, vertigo: dexamethasone Drug induced, hepatic or renal failure: prochlorperazine, haloperidol GERD: PI or HZ antagonist Gastric stasis: metoclopramide Bowel obstruction: metoclopramide, dexamethasone, octreotide</td>
</tr>
<tr>
<td>Pain</td>
<td>Hot and cold compresses, music therapy, relaxation techniques, individualized program of physical activity designed to improve flexibility, strength and endurance</td>
<td>Nociceptive pain: non-opioids (NSAIDs, acetaminophen), weak opioids (codeine, hydrocodone, oxycodone), strong opioids (morphine, hydromorphone, oxycodone, fentanyl) Neuropathic pain: anticonvulsants (gabapentin, pregabalin), antidepressants (TCAs, SSRIs), steroids (dexamethasone) Bony pain: non-opioids, weak opioids, bisphosphonates, radiation therapy</td>
</tr>
<tr>
<td>Pruritus</td>
<td>Bathing with tepid water, avoid soap, bath oils; sodium bicarbonate for jaundice</td>
<td>Antihistamines, phenothiazines, topical corticosteroids, calamine lotion</td>
</tr>
<tr>
<td>Weakness</td>
<td>Modify environment and activities to decrease energy expenditure</td>
<td>Treat insomnia, anemia, depression; consider psychostimulants</td>
</tr>

Note: Serum creatinine does not reflect creatinine clearance in the elderly. Instead, use:

\[\text{CrCl} = \frac{(\text{weight in kg}) \times (140 – \text{age})}{(\text{serum creatinine in } \mu\text{mol/L})}\]

Multiply by 0.85 for females.
Pharmacodynamics

Drug Sensitivity
- changes in pharmacokineti cs as well as intrinsic sensitivity lead to altered drug responses
- increased sensitivity to warfarin, sedatives, antipsychotics, digoxin and narcotics
- decreased sensitivity to β-blockers in majority of elderly patients, though some may have increased sensitivity

Decreased Homeostasis
- poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)

Polypharmacy

Definition
- prescription, administration or use of many medications at the same time

Epidemiology
- in Canada, over 25% of elderly women and about 20% of elderly men reported using ≥3 medications
- hospitalized elderly are given an average of 10 medications during admission

Risk Factors for Non-Compliance
- risk of non-compliance correlates with medication factors, not age
  - number of medications – compliance with 1 medication is 80%, but drops to 25% with ≥6 medications
  - increased dosing frequency, complicated container design, financial constraints, and cognitive impairment

Adverse Drug Reactions (ADRs)
- any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
- risk factors in the elderly
  - intrinsic: co-morbidities, age-related changes in pharmacokinetics and pharmacodynamics
  - extrinsic: number of medications, multiple prescribers, unreliable drug history
- 90% of ADRs are from: ASA, analgesics, anticoagulants, antimicrobials, antineoplastics, digoxin, diuretics, hypoglycemics, steroids

Preventing Polypharmacy
- consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
- consider patient: other medications, clinical indications, medical co-morbidities
- consider patient-drug interaction risk factors for ADRs
- review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
- avoid treating an ADR with another medication

Inappropriate Prescribing in the Elderly

Epidemiology
- the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

Beers Criteria
- a list of medications to avoid in adults 65 and older due to safety concerns
- examples include long-acting benzodiazepines, strong anticholinergics, high-dose sedatives
- the elderly are also often under-treated (ACEI, ASA, β-blockers, thrombolytics, warfarin)
## Common Medications

### Table 12. Common Medications

| Drug Name      | Brand Name       | Dosing Schedule          | Indications                                                                 | Contraindications                                           | Side Effects                                                                                          | Mechanism of Action                                      |
|---------------|------------------|--------------------------|------------------------------------------------------------------------------|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|

Basic Anatomy Review

Figure 1. Vulva and perineum

A. EXTERNAL GENITALIA (Figure 1)
- referred to collectivley as the vulva
- blood supply: internal pudendal artery
- sensory innervation: pudendal nerve
- lymphatic drainage: inguinal nodes

B. VAGINA
- muscular canal extending from cervix to vulva, anterior to rectum and posterior to bladder
  - lined by rugated, stratified-squamous epithelium
  - upper vagina separated by cervix into anterior, posterior and lateral fornices
  - blood supply: vaginal branch of internal pudendal artery with anastomoses from uterine, inferior vesical and middle rectal arteries

C. UTERUS
- thick walled, muscular organ between bladder and rectum, consisting of two major parts:
  - uterine corpus
    - blood supply: uterine artery (branch of the internal iliac artery)
  - cervix
    - blood supply: cervical branch of uterine artery
  - supported by the pelvic diaphragm, the pelvic organs and 4 paired sets of ligaments
  - round ligaments: travel from anterior surface of uterus, through broad ligaments and inguinal canals then terminate in the labia majora
    - function: anteversion
  - blood supply: Sampson’s artery (branch of uterine artery running through round ligament)
  - uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
    - function: mechanical support for uterus and contain autonomic nerve fibres
  - cardinal ligaments: extend from lateral pelvic walls and insert into lateral cervix and vagina
    - function: mechanical support, prevent prolapse
  - broad ligaments: pass from lateral pelvic wall to sides of uterus; contain fallopian tube, round ligament, ovarian ligament, nerves, vessels and lymphatics
    - infundibulopelvic ligament: continuous tissue that connects ovary to pelvic wall
    - contains the ovarian artery, ovarian vein, ovarian plexus, lymphatic vessels
  - position of the uterus (Figure 3)
    - antverted (majority)
    - retroverted

Figure 2. External genital organs

D. FALLOPIAN TUBES
- 8-14 cm muscular tubes extending laterally from the uterus to ovary
- interstitial, isthmic, ampullary and infundibular segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

E. OVARIES
- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

Figure 3. Positioning of uterus

Anteversion: forward-tilted uterus.
Anteflexion: bending of uterus so the fundus is thrust forward.
Retroversion: backward-tilted uterus.
Retroflexion: bending of uterus so the fundus is thrust backward.

Figure 4. Vascular supply

"Water under the bridge"
The ureters run posterior to the uterine arteries.

Menstruation

Stages of Puberty

- see Pediatrics, P31
- adrenarche: increase in secretion of adrenal androgens; usually precedes gonadarche by 2 yr
- gonadarche: increased secretion of gonadal sex steroids; ~age 8
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 yr following breast budding
Figure 5. Events of the normal menstrual cycle

**Menstrual Cycle**

**FOLLICULAR/PROLIFERATIVE PHASE (Variable Duration)**

**Estrogen**

ESTROGEN is the main hormone in the follicular/proliferative phase and is stimulated by FSH. Increased estrogen mainly decreases FSH. The majority of estrogen is secreted by the dominant follicle.

**Estrogen effects:**
- On the follicles in the ovaries:
  - Reduces atresia
- On the endometrium:
  - Proliferation of glandular and stromal tissue
- On all target tissues:
  - Decreases E receptors

**Progesterone**

PROGESTERONE is the main hormone in the luteal/secretory phase and is stimulated by LH. Increased progesterone mainly decreases LH and is secreted by the corpus luteum (remnant of dominant follicle).

**Progesterone effects:**
- On the endometrium:
  - Cessation of mitoses (stops building endometrium up)
  - “Organization” of glands (initiates secretions from glands)
  - Inhibits macrophages, interleukin-8 and enzymes from degrading endometrium
- On all target tissues:
  - Decrease E receptors (the “anti-estrogen” effect)
  - Decrease P receptors
Premenstrual Syndrome (PMS)

- **synonyms:** "ovarian cycle syndrome," "menstrual molimina" (moodiness)

**Etiology**
- not completely understood, multifactorial, genetics likely play a role
- CNS-mediated neurotransmitter interactions with sex steroids (progesterone, estrogen and testosterone)
- serotonergic dysregulation – currently most plausible theory

**Diagnostic Criteria for Premenstrual Syndrome**
- at least one affective and one somatic symptom during the 5 d before menses in each of the three prior menstrual cycles
  - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
  - somatic: breast tenderness, abdominal bloating, headache, swelling of extremities
- symptoms relieved within 4 d of onset of menses
- symptoms present in the absence of any pharmacologic therapy, drug or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or economic performance

**Treatment**
- goal: symptom relief
- psychological support
- diet/supplements
  - avoid sodium, simple sugars, caffeine and alcohol
  - calcium (1200-1600 mg/d), magnesium (400-800 mg/d), vitamin E (400 IU/d), vitamin B6
- medications
  - NSAIDs for discomfort, pain
  - spironolactone for fluid retention: used during luteal phase
  - SSRI antidepressants: used during luteal phase x 14 d or continuously
  - OCP: primarily beneficial for physical/somatic symptoms
  - danazol: an androgen that inhibits the pituitary-ovarian axis
  - GnRH agonists if PMS is severe and unresponsive to treatment
- mind/body approaches
  - regular aerobic exercise
  - cognitive behavioural therapy
  - relaxation, light therapy biofeedback and guided imagery
- herbal remedies (variable evidence)
  - evening primrose oil, black cohosh, St. John's wort, kava, ginkgo, agnus castus fruit extract
- BSO if symptoms severe

Premenstrual Dysphoric Disorder (PMDD)

**Definition**
- official diagnosis in the DSM-IV-TR
- described as a more severe form of PMS with specific diagnostic criteria
- treatment with SSRIs (first line), and Yaz® OCP (highly effective)
Differential Diagnoses of Common Presentations

Abnormal Uterine Bleeding (AUB)

- see Disorders of Menstruation, GY14
- definition: change in frequency, duration or amount of menstrual flow
- classified as amenorrhea, oligomenorrhea, menorrhagia/hypermenorrhea, hypomenorrhea, metrorrhagia, menometrorrhagia, polymenorrhea, postmenopausal bleeding
  - hypomenorrhea: bleeding that is decreased in amount
  - oligomenorrhea: bleeding occurring at intervals >35 d
  - polymenorrhea: bleeding occurring at intervals <21 d
  - menorrhagia/hypermenorrhea: bleeding at regular intervals that is prolonged in duration (>7 d) or excessive in amount (>80 cc per menstrual cycle)
  - metrorrhagia: bleeding at irregular intervals, particularly between expected menstrual periods
  - menometrorrhagia: excessive bleeding at usual time of menstrual periods and at other irregular intervals
  - postmenopausal bleeding: any bleeding that presents >1 yr after menopause; must rule out endometrial cancer

Dysmenorrhea

- see Disorders of Menstruation, GY15
- primary/idiopathic
- secondary (acquired)
  - endometriosis
  - adenomyosis
  - uterine polyps
  - uterine anomalies (e.g. non-communicating uterine horn)
  - leiomyoma
  - intrauterine synechiae
  - ovarian cysts
  - cervical stenosis
  - imperforate hymen, transverse vaginal septum
  - pelvic inflammatory disease (PID)
  - IUD (copper)
  - foreign body

Vaginal Discharge/Pruritus

- see Gynecological Infections, GY24
- physiologic discharge and cervical mucus production
- non-physiologic
  - genital tract infection
    - vulvovaginitis: candidiasis, trichomoniasis, bacterial vaginosis (BV), polymicrobial superficial infection
    - chlamydia, gonorrhea
    - pyosalpinx, salpingitis
  - genital tract inflammation (non-infectious)
  - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis, desquamative inflammatory vaginitis, focal vulvitis
  - neoplasia: vulvar, vaginal, cervical, endometrial
  - systemic: toxic shock syndrome, Crohn's disease, collagen disease, dermatologic (e.g. lichen sclerosis)
  - IUD, OCP (secondary to progesterone)
Pelvic Pain

- Acute
  - Gynecological
    - Appendicitis
    - Mesenteric adenitis
    - Diverticulitis
  - Non-gynecological
    - UTI (e.g., cystitis, pyelonephritis)
    - Renal colic
- Chronic
  - Pregnancy-related
    - Labour
    - Ectopic pregnancy
  - Gynecological
    - Chronic PID
    - Endometritis
    - Dysmenorrhea
  - Non-gynecological
    - Referred pain
    - Urinary retention

Adnexal
- Mittelschmerz
- Ruptured ovarian cyst
- Ruptured ectopic pregnancy
- Hemorrhage into cyst/neoplasm
- Ovarian/tubal torsion

Uterine
- Fibroid degeneration
- Torsion of pedunculated fibroid
- Pyometra/hematometra

Infectious
- Acute PID
- Endometritis

20% of chronic pelvic pain patients have a history of previous sexual abuse/assault. Remember to ask about it!

Pelvic Mass

- Ovarian
  - Functional Cysts
    - (always benign)
    - Corpus luteum cyst
    - Follicular cyst
    - Theca lutein cyst
    - Hemorrhagic cyst
  - Neoplasm
    - Benign
      - Dermoid cyst
        - (most common)
      - Malignant
        - Epithelial cell
          - (most common in >40 yr)
        - Germ cell
          - (most common in <20 yr)
      - PCOS
      - Endometrioma
      - Tube-ovarian abscess
      - Luteoma of pregnancy
  - Other
    - PCOS
    - Endometrioma
    - Hematometra/pyometra
    - Endometrial cancer
    - Imperforate hymen

- Uterine
  - Symmetrical
    - Pregnancy
    - Adenomyosis
    - Hematometra/pyometra
    - Endometrial cancer
    - Imperforate hymen
  - Asymmetrical
    - Leiomyoma
    - Leiomyosarcoma

- Other
  - Gynecological
    - Ectopic pregnancy
    - Pelvic adhesions
    - (resulting in fluid entrapment)
  - Paratubal cysts
  - Pyosalpinx/Hydrosalpinx
  - Primary fallopian tube neoplasms

Gastrointestinal
- Appendiceal abscess
- Diverticular abscess
- Diverticulitis, diverticulosis
- Carcinoma of rectum/colon

Genitourinary
- Distended bladder
- Pelvic kidney
- Carcinoma of bladder
- Lymphoma

Pelvic Pain

- Acute
  - Gynecological
  - Non-gynecological
- Chronic
  - Pregnancy-related
  - Gynecological
  - Non-gynecological

Pelvic Mass

- Ovarian
  - Functional Cysts
    - (always benign)
    - Corpus luteum cyst
    - Follicular cyst
    - Theca lutein cyst
    - Hemorrhagic cyst
  - Neoplasm
    - Benign
      - Dermoid cyst
        - (most common)
      - Malignant
        - Epithelial cell
          - (most common in >40 yr)
        - Germ cell
          - (most common in <20 yr)
      - PCOS
      - Endometrioma
      - Tube-ovarian abscess
      - Luteoma of pregnancy
  - Other
    - PCOS
    - Endometrioma
    - Hematometra/pyometra
    - Endometrial cancer
    - Imperforate hymen

- Uterine
  - Symmetrical
    - Pregnancy
    - Adenomyosis
    - Hematometra/pyometra
    - Endometrial cancer
    - Imperforate hymen
  - Asymmetrical
    - Leiomyoma
    - Leiomyosarcoma

- Other
  - Gynecological
    - Ectopic pregnancy
    - Pelvic adhesions
    - (resulting in fluid entrapment)
  - Paratubal cysts
  - Pyosalpinx/Hydrosalpinx
  - Primary fallopian tube neoplasms

Gastrointestinal
- Appendiceal abscess
- Diverticular abscess
- Diverticulitis, diverticulosis
- Carcinoma of rectum/colon

Genitourinary
- Distended bladder
- Pelvic kidney
- Carcinoma of bladder
- Lymphoma
**Dyspareunia**

Dyspareunia can be classified into three main categories: introital, midvaginal, and deep. Each category may involve different underlying conditions:

- **Introital:**
  - Inadequate lubrication
  - Vaginismus
  - Rigid/intact hymen
  - Bartholin’s or Skene’s gland infection
  - Lichen sclerosis
  - Vulvovaginitis: atrophic (hypoestrogen), chemical, infectious (chlamydia, trichomoniasis)

- **Midvaginal:**
  - Urethritis
  - Short vagina
  - Trigonitis
  - Congenital abnormality of the vagina (e.g., vaginal septum)

- **Deep:**
  - Endometriosis
  - Adenomyosis
  - Leiomyomata/fibroids
  - PID (acute vs. chronic)
  - Hydrosalpinx
  - Tubo-ovarian abscess
  - Uterine retroversion
  - Ovarian cyst

**Bloodwork**

- **CBC:** evaluation of severity of abnormal uterine bleeding, pre-op investigation ± ferritin if anemic
- **β-hCG:** investigation of possible pregnancy, ectopic pregnancy, ovarian germ cell tumour
  - work-up for GTD/GTN
  - monitored after medical management of ectopic pregnancy and GTN to assess for cure or recurrence
- **LH, FSH, TSH, free T4, prolactin, DHEA, testosterone, estradiol, androstenedione:** investigation of amenorrhea, menstrual irregularities, menopause, infertility

**Imaging**

**Ultrasound (U/S):**

- transabdominal or transvaginal U/S is the imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
  - detects early pregnancy if β-hCG ≥1500 (β-hCG must be ≥6500 for transabdominal U/S)
- may be used to identify pelvic pathology
  - identify ectopic pregnancy, intrauterine pregnancy
  - assess uterine, adnexal, cul-de-sac, ovarian masses (e.g., solid or cystic)
  - determine endometrial thickness, locate/characterize fibroids
  - monitor follicles during assisted reproduction
  - assess endometrial lining in postmenopausal women

**Sonohysterography (SHG):**

- saline infusion into endometrial cavity expands endometrial cavity, improving visualization of uterus and fallopian tubes
- useful for investigation of:
  - abnormal uterine bleeding (AUB)
  - uncertain endometrial findings on transvaginal U/S
  - infertility (tubal patency)
  - congenital/acquired uterine abnormalities (e.g., fibroids, endometrial polyps)
- easily done, minimal cost, well-tolerated, sensitive and specific
- frequently avoids need for diagnostic hysteroscopy

**Hysterosalpingography (HSG):**

- x-ray contrast introduced through the cervix into the uterus
- used for evaluation of size, shape, configuration of uterus, congenital uterine abnormalities, tubal patency, or obstruction
- useful for investigation of infertility
- often replaced by sonohysterogram with Echovist® to look at tubes

Every woman of childbearing age presenting to ER with abdominal or pelvic pain should have β-hCG measured. Check for STIs before performing SHG and HSG to prevent PID in high-risk individuals. Consider pre-treatment with doxycycline.
Common Procedures

Genital Tract Biopsy

Vulvar Biopsy
- performed under local anesthetic
- Keyes/punch biopsy
- hemostasis achieved with local pressure and Monsel's solution (ferric sulfate), silver nitrate or suture (rarely)

Vaginal Biopsy and Cervical Biopsy
- anesthetic not necessary
- punch biopsy or biopsy forceps
- hemostasis with Monsel's solution and pressure

Endometrial Biopsy
- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
  - pre-treatment with misoprostol (Cytotec®) if nulliparous or postmenopausal
- more invasive procedure (D&C) may be done in the office or operating room ± hysteroscopy

Colposcopy
- diagnostic use
  - magnifies surface structures of the vulva, vagina, cervix and perianal region
  - 1% acetic acid wash applied to cervix dehydrates cells and reveals “acetowhite” areas that correspond to increased nucleus-to-cytoplasm ratio (abnormal)
  - allows biopsy of acetowhite lesions for early identification of dysplasia and cancer
- therapeutic use
  - cryotherapy: nitrous oxide or carbon dioxide freezes dysplastic lesions, genital warts
  - laser vaporization: used to treat dysplastic lesions of the exocervix and benign ectropion
  - loop electrosurgical excision procedure (LEEP): excision of transformation zone with the cervical lesion; provides a specimen for pathological examination

Vacuum Aspiration
- procedure to empty the contents of the uterus through a plastic or metal cannula (thin tube) attached to a vacuum source

Indications
- termination of pregnancy in 1st trimester

Manual Vacuum Aspiration (≤10 wk gestation)
- source of vacuum: hand-held, portable aspirator
- anesthesia: local (paracervical block) in most cases
- can be performed in an office setting
- suction curette connected to aspirator empties the uterus

Electric Vacuum Aspiration (≤13 wk gestation)
- source of vacuum: electric pump
- anesthesia: local (paracervical block) and conscious sedation or general anesthetic
- dilatation of cervix with dilators of increasing diameter
- suction curette connected to electric pump empties the uterus
- after aspiration, uterine cavity can be gently explored with sharp curette

Complications
- bleeding
- infection
- perforation of uterus, laceration of cervix
  - reduce risk with preprocedural cervical dilatation (misoprostol or osmotic dilators)
- retained products of conception
  - requires reaspiration, rare (2/1000)
**Dilatation and Curettage (D&C)**

- determine depth with uterine sound prior to procedure
- dilatation of cervix with dilators of increasing diameter
- scrape entire uterine cavity with sharp curette
- anesthesia: general or local

**Indications**

- diagnostic (rarely done without hysteroscopy)
  - abnormal uterine bleeding (AUB)
  - dysfunctional uterine bleeding (DUB)
- therapeutic
  - removal of retained products of conception following abortion
  - termination of pregnancy in 1st trimester
  - removal of small uterine polyps or pedunculated submucosal fibroids

**Complications**

- bleeding
- infection
- perforation of uterus, laceration of cervix
  - reduce risk with preoperative misoprostol (Cytotec®) inserted per vagina to soften cervix and stimulate uterine contraction
- incompetent cervix – extremely rare
- Asherman's syndrome

---

**Laparoscopy**

- laparoscope (fibre optic camera) used to view pelvic/abdominal contents through small incisions

**Indications**

- diagnostic
  - evaluation of infertility, pelvic pain, pelvic masses, congenital anomalies, hemoperitoneum and endometriosis
- therapeutic
  - tubal ligation
  - lysis of adhesions
  - excision of ectopic pregnancy
  - excision/ablation of endometriosis
  - retrieval of lost IUDs
  - cystectomy, salpingo-oophorectomy and hysterectomy
  - myomectomy
  - treatment of stress urinary incontinence

**Contraindications**

- bowel obstruction
- large hemoperitoneum
- clinically unstable patient
- inability to maintain pneumoperitoneum
- multiple previous abdominal surgeries (i.e. adhesions)

**Complications**

- general anesthesia related
- insufflation of the preperitoneal abdominal wall
- injury to surrounding structures (e.g. aorta, inferior epigastric vessels, bowel, bladder, ureters)
- may need to convert to laparotomy
- infection

---

**Hysteroscopy**

- flexible or rigid scope inserted through cervix into uterus to visualize uterine cavity
- distension medium is used to allow inspection of this potential space

**Indications**

- diagnostic
  - detection of uterine anomalies or pathology (e.g. infertility work-up)
  - AUB
  - DUB
- therapeutic
  - removal of uterine polyps, fibroids, adhesions, septa
  - endometrial ablation
Complications
- perforation of uterus, laceration of cervix
- bleeding
- infection
- absorption of excess distension medium (when sugar solutions utilized, e.g. glucose, mannitol)
  - fluid overload, hyponatremia
    - procedure should be abandoned if the fluid deficit rises to 1 L; consider stopping at 500 cc
- air emboli
- anaphylactic shock

Endometrial Ablation
- alternative invasive procedure to hysterectomy for treatment of AUB; performed as outpatient
- rationale is to coagulate or resect the endometrium basalis layer to prevent monthly build-up and reduce menstrual losses

Methods
- rollerball electrode coagulation or resection
- microwave endometrial ablation
- thermoablation (hot water), balloon ablation
- laser photocoagulation

Complications
- infection
- injury to pelvic viscera if uterus perforated
- hematometra
- absorption of excess distention medium \(\rightarrow\) fluid overload, hyponatremia
- failure (i.e. bleeding/menorrhagia persists)
- recurrence of symptoms (~20% at 5 yr), may eventually require hysterectomy

Hysterectomy

Indications
- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervix)

Complications
- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)

Approaches
1. vaginal vs. abdominal
  - indications for vaginal approach: mobile uterus, uterine size <12 wk
  - advantages of vaginal approach: less pain, faster recovery time, allows for simultaneous repair of rectocele/cystocele/enterocele, improved aesthetics
2. open vs. laparoscopic-assisted
  - advantages of laparoscopy: less pain, faster recovery, improved aesthetics, shorter hospital stay
3. robotic
  - similar advantages to laparoscopy
  - more dexterous

Approaches to Hysterectomy
- Abdominal hysterectomy: uterus removed via transverse or vertical laparotomy
- Vaginal hysterectomy: uterus removed via vagina. No visualization or entry into abdomen unless laparoscopic-assisted
- Laparoscopic/Robotic: uterus removed via vagina or morcellation

</tbody>
</table>

Primary Amenorrhea

No menses by age 14 in absence of 2º sexual characteristics or no menses by age 16 with 2º sexual characteristics.

Secondary Amenorrhea

No menses for >6 mo or 3 cycles after documented menarche.

Oligomenorrhea

Episodic vaginal bleeding occurring at intervals >35 d.

Prolactinoma Symptoms

Galactorrhea, visual changes, headache.

2º amenorrhea is pregnancy until proven otherwise.

Functional hypothalamic amenorrhea is the most common cause of amenorrhea.
Investigations

**Amenorrhea**

### 1° Amenorrhea
- **History and Physical Exam**
  - **β-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)**
  - **Progesterone challenge to assess estrogen status**
    - Medroxyprogesterone acetate (Provera®) 10 mg PO OD for 10-14 d
    - Any uterine bleed within 2-7 d after completion of Provera® is considered to be a positive test/withdrawal bleed
    - Withdrawal bleed suggests presence of adequate estrogen to thicken the endometrium; thus withdrawal of progesterone results in bleeding
    - If no bleeding occurs, there may be inadequate estrogen (hypoestrogenism) or excessive androgens
  - **Karyotype:** indicated if premature ovarian failure or absent puberty
  - **U/S to confirm normal anatomy, identify PCOS**

### 2° Amenorrhea
- **β-hCG**
  - **Negative**
    - Prolactin (PL) Abnormal
    - Progesterone challenge
  - **High**
    - HP axis dysfunction
      - MRI hypothalamus, pituitary
      - Measure other pituitary hormones
      - Common etiology:
        - Weight loss
        - Excessive exercise
        - Systemic diseases
    - Premature ovarian failure
      - MRI MRKH syndrome
      - AIP
      - Müllerian dysgenesis
      - Mullerian agenesis
      - Transverse vaginal septum
      - Imperforate hymen
      - Cervical agenesis

### Treatment

**Table 4. Management of Amenorrhea**

<table>

<td></td>
</tr>
</tbody>
</table>
| AIS | • Gonadal resection after puberty  
• Psychological counselling  
• Creation of neo-vagina |
| Anatomical | • Surgical management |
  - Imperforate hymen  
  - Transverse vaginal septum  
  - Cervical agenesis |
| Müllerian dysgenesis (MRKH syndrome) | • Psychological counselling  
• Creation of neo-vagina with dilation  
• Diagnostic study to confirm normal urinary system and spine |
| **2° AMENORRHEA** | |
| Uterine defect | • Evaluation with hysterosalpingography or sonohysterography  
• Hysteroscopy: excision of synechiae |
| Asherman’s syndrome | |
| HP-axis dysfunction | • Identify modifiable underlying cause  
• Combined OCP to decrease risk of osteoporosis, maintain normal vaginal and breast development |
| Premature ovarian failure | • Screen for diabetes mellitus, hypothyroidism, hypoparathyroidism, hypocorticalism  
• Hormonal therapy with estrogen + progesterin to decrease risk of osteoporosis. Can use OCP |
| Hyperprolactinemia | • MRI/CT head to r/o lesion  
• If no demonstrable lesions by MRI:  
  - Bromocriptine, cabergoline if fertility desired  
  - Combined OCPs if no fertility desired  
• Demonstrable lesions by MRI: surgical management |
| Polycystic ovarian syndrome | |
Abnormal Uterine Bleeding (AUB)

![Diagram of Abnormal Uterine Bleeding](https://example.com/diagram)

<table>
<thead>
<tr>
<th>Anovulatory</th>
<th>Ovulatory</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Incidence</strong></td>
<td>90%</td>
</tr>
<tr>
<td><strong>Definition</strong></td>
<td>Unpredictable endometrial bleeding of variable flow and duration; sex steroids are produced but not cyclically, resulting in irregular bleeding</td>
</tr>
<tr>
<td><strong>Etiology</strong></td>
<td>PCOS, Thyroid dysfunction, Elevated prolactin levels, Rare estrogen-producing tumors, Stress, weight loss, exercise, Liver and kidney disease</td>
</tr>
<tr>
<td><strong>Pathophysiology</strong></td>
<td>Estrogen-dependent breakthrough bleeding: chronic estrogen production unopposed by adequate progesterone production → continued proliferation of the endometrium → thickened endometrium outgrows its blood supply → focal necrosis with partial shedding not uniformly → bleeding is usually irregular, prolonged, and heavy</td>
</tr>
</tbody>
</table>

**Investigations**
- CBC, serum ferritin
- β-hCG
- TSH, free T₃
- coagulation profile (especially in adolescents): rule out von Willebrand’s disease
- prolactin if amenorrheic
- FSH, LH
- serum androgens (especially free testosterone)
- day 21 (luteal phase) progesterone to confirm ovulation
- Pap test
- pelvic U/S: detect polyps, fibroids; measure endometrial thickness (postmenopausal)
- SHG: very sensitive for intrauterine pathology (polyps, submucous fibroids)
- HSG
- endometrial biopsy: consider biopsy in women >40 yr
  - must do endometrial biopsy in all women presenting with postmenopausal bleeding to exclude endometrial cancer
- D&C: not for treatment; diagnosis only (usually with hysteroscopy)
Treatment
- treat underlying disorders
  - if anatomic lesions and systemic disease have been ruled out, consider dysfunctional uterine bleeding (DUB)
- medical
  - mild DUB (see sidebar)
    - NSAIDs
    - anti-fibrinolytic (e.g. Cyklokapron®) at time of menses
    - combined OCP
    - progestins (Provera®) on first 10-14 d of each month if oligomenorrheic
    - Mirena® IUD
    - danazol
  - acute, severe DUB
    - replace fluid losses, consider admission
    - a) estrogen (Premarin®) 25 mg IV q4h x 24h with Gravol® 50 mg IV/PO q4h
    - b) Ovral®, or any OCP with minimum 50 µg estradiol 1 tab PO q4h x 24 h with Gravol® 50 mg IV/PO q4h
      - taper Ovral® to 1 tab tid x 2 d → bid x 2 d → OD
    - after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
    - clomiphene citrate
      - consider in patients who are anovulatory and who wish to get pregnant
- surgical
  - endometrial ablation; consider pretreatment with danazol or GnRH agonists
  - if finished childbearing
  - repeat procedure may be required if symptom reoccur
  - hysterectomy: definitive treatment

Dysmenorrhea

Etiology
- see Differential Diagnoses of Common Presentations, GY6

<table>
<thead>
<tr>
<th></th>
<th>Primary Dysmenorrhea</th>
<th>Secondary Dysmenorrhea</th>
</tr>
</thead>
<tbody>
<tr>
<td>Features</td>
<td>Menstrual pain in absence of organic disease. Begins 6 mo-2 yr after menarche (once ovulatory cycles established)</td>
<td>Menstrual pain due to organic disease. Usually begins in women who are in their 20s, worsens with age May improve temporarily after childbirth</td>
</tr>
<tr>
<td>Signs and Symptoms</td>
<td>Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h) Associated symptoms: nausea, vomiting, altered bowel habits, headaches, fatigue (prostaglandin-associated)</td>
<td>Associated dyspareunia, abnormal bleeding, infertility</td>
</tr>
<tr>
<td>Diagnosis</td>
<td>Associated dyspareunia, abnormal bleeding, infertility</td>
<td>Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus (findings are rare in women &lt; 20 yr) U/S, laparoscopy and hysteroscopy may be necessary to establish the diagnosis</td>
</tr>
<tr>
<td>Treatment</td>
<td>PG synthetase inhibitors (e.g. Anaprox®): should be started before onset of pain OCP: suppress ovulation/reduce menstrual flow</td>
<td>Treat underlying cause</td>
</tr>
</tbody>
</table>
Endometriosis

Etiology
- not fully understood
- proposed mechanisms (combination likely involved)
  - retrograde menstruation (Sampson’s theory)
    - seeding of endometrial cells by transtubal regurgitation during menstruation
    - endometrial cells most often found in dependent sites of the pelvis
  - immunologic theory: altered immunity may limit clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
  - metaplasia of coelomic epithelium
    - undefined endogenous biochemical factor may induce undifferentiated peritoneal cells to develop into endometrial tissue
  - extrapelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
    - e.g. ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

Epidemiology
- incidence: 15-30% of pre-menopausal women
- mean age at presentation: 25-30 yr
- regresses after menopause

Risk Factors
- family history (7-10 fold increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset) – resolve with treatment of anomaly
- nulliparity
- age >25 yr

Sites of Occurrence
- ovaries: 60% patients have ovarian involvement
- broad ligament, vesicouterine fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs

Clinical Features
- may be asymptomatic
- history
  - menstrual symptoms
    - cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 h) and continue throughout and after flow
    - secondary dysmenorrhea
    - sacral backache with menses
    - pain may eventually become chronic, worsening perimenstrually
    - premenstrual and postmenstrual spotting
    - deep dyspareunia
  - infertility
    - 30-40% of patients with endometriosis will be infertile
    - 15-30% of those who are infertile will have endometriosis
  - bowel and bladder symptoms
    - frequency, dysuria, hematuria
    - diarrhea, constipation, hematochezia, dyschezia
- physical
  - tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
  - fixed retroversion of uterus
  - firm, fixed adnexal mass (endometrioma)
  - physical findings not present in adolescent population

Investigations
- definitive diagnosis requires:
  - direct visualization of lesions typical of endometriosis at laparoscopy
  - biopsy and histologic exam of specimens (2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages)
- laparoscopy
  - mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac or anywhere in the pelvis
  - endometrioma: “chocolate” cysts on the ovaries
  - “powder-burn” lesions on the peritoneal surface
  - early white lesions and clear blebs
  - peritoneal “pockets”
- CA-125
  - may be elevated in patients with endometriosis
Treatment
- depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility and impact to GI/GU systems (e.g. intestinal obstruction)
- medical
  - NSAIDs (e.g. naproxen sodium – Anaprox®)
  - pseudopregnancy
    - cyclic/continuous estrogen-progestin (OCP)
    - medroxyprogesterone (Depo-Provera®)
    - dienogest (Visanne®)
  - pseudomenopause
    - 2nd line: only short-term (<6 mo) due to osteoporotic potential with prolonged use, unless combined with add-back therapy (e.g. estrogen/progesterone or SERM). If long-term use required, add-back estrogen+progesterone
    - danazol (Danocrine®): weak androgen
      - side effects: weight gain, fluid retention, acne, hirsutism, voice change
    - leuprolide (Lupron®): GnRH agonist (suppresses pituitary)
      - side effects: hot flashes, vaginal dryness, reduced libido
      - can use ≥12 mo with add-back progestin or estrogen
- surgical
  - conservative laparoscopy using laser, electrocautery ± laparotomy
  - ablation/resection of implants, lysis of adhesions, ovarian cystectomy of endometriomas
  - definitive: bilateral salpingo-oophorectomy ± hysterectomy
  - ± follow-up with medical treatment for pain control not shown to impact on preservation of fertility
  - best time to become pregnant is immediately after conservative surgery

Adenomyosis
- synonym: “endometriosis interna” (uterine wall may be diffusely involved)

Epidemiology
- 15% of females >35 yr old; found in 20-40% of hysterectomy specimens
- mean age at presentation: 40-50 yr old (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

Clinical Features
- often asymptomatic
- menorrhagia, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm, mobility not restricted, no associated adnexal pathology
- Halban sign: tender, softened uterus on premenstrual bimanual exam

Investigations
- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

Treatment
- iron supplements as necessary
- analgesics, NSAIDs
- OCP, medroxyprogesterone (Depo-Provera®)
- low dose danazol 100-200 mg PO OD (trial x 4 mo)
- GnRH agonists (e.g. leuprolide)
- definitive: hysterectomy (no conservative surgical treatment)

Leiomyomata (Fibroids)

Epidemiology
- diagnosed in approximately 40-50% of pre-menopausal women >35 yr
- more common in African Americans, where they are also larger and occur at earlier age
- common indication for major surgery in females
- minimal malignant potential (1:1000)
- typically regress after menopause; enlarging fibroids in a postmenopausal woman should prompt consideration of malignancy
  - 50% of leiomyosarcomas originate from within fibroids
**Pathogenesis**

- estrogen stimulates monoclonal smooth muscle proliferation
- progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumour outgrows blood supply)
  - hyaline degeneration (most common degenerative change)
  - cystic degeneration (from breakdown of hyaline)
  - red/carnearious degeneration (hemorrhage into tumour, may occur in pregnancy)
  - fatty degeneration
  - calcification
  - sarcomatous degeneration (rare)
- parasitic myoma: tumour becomes attached to another organ (typically omentum or small bowel mesentery), develops new blood supply and loses connection to uterus

**Clinical Features**

- majority asymptomatic (60%), often discovered as incidental finding on pelvic exam or U/S
- abnormal uterine bleeding (30%): dysmenorrhea, menorrhagia
- pressure/bulk symptoms (20-50%)
  - pelvic pressure/heaviness
  - increased abdominal girth
  - urinary frequency and urgency
  - acute urinary retention (extremely rare but surgical emergency!)
  - constipation, bloating (rare)
- acute pelvic pain
- fibroid degeneration
- fibroid torsion (pedunculated subserosal)
- infertility, recurrent pregnancy loss
- pregnancy complications (potential enlargement and increased pain, obstructed labour, difficult C-section)

**Investigations**

- bimanual exam: uterus asymmetrically enlarged, usually mobile
- CBC: anemia
- U/S: to confirm diagnosis and assess location of fibroids
- sonohysterogram: useful for differentiating endometrial polyps from submucosal fibroids, or if intracavitary growth
- endometrial biopsy to rule out uterine cancer for abnormal uterine bleeding (especially if intracavitary growth)
- MRI is used for pre-op planning (e.g. before myomectomy)

**Treatment**

- only if symptomatic, rapidly enlarging, if menorrhagia or menometrorrhagia, if intracavitary growth
- treat anemia if present
- conservative approach (watch and wait) if:
  - symptoms absent or minimal
  - fibroids <6-8 cm or stable in size
  - not submucosal (submucosal fibroids are more likely to be symptomatic)
  - currently pregnant due to increased risk of bleeding (follow-up U/S if symptoms progress)
- medical approach
  - antiprostaglandins (ibuprofen, other NSAIDs)
  - tranexamic acid (Cyklokapron®)
  - OCP/Depo-Provera®
  - GnRH agonist: leuprolide (Lupron®), danazol (Danocrine®)
    - short-term use only (6 mo)
    - often used pre-myomectomy or pre-hysterectomy to reduce fibroid size
    - reduced bleeding
  - ulipristal acetate: a partial progesterone receptor agonist
- interventional radiology approach
  - uterine artery embolization (occludes both uterine arteries) → shrinks fibroids by 50% at 6 mo; improves menorrhagia in 90% of patients within 1-2 mo; not an option in women considering childbearing
- surgical approach
  - myomectomy (hysteroscopic, transabdominal or laparoscopic); preserves fertility
  - hysteroscopic resection of fibroid and endometrial ablation for menorrhagia
  - hysterectomy (see Hysterectomy, GY11)
- note: avoid operating on fibroids during pregnancy (due to vascularity and potential pregnancy loss); expectant management usually best

**Figure 11. Possible anatomic locations of uterine leiomyomata**

The effect of pregnancy on fibroid size is variable.

**Ulipristal Acetate versus Leuprolide Acetate for Uterine Fibroids**

**Study**: Phase III, double-blind RCT of the efficacy and side-effect profile of ulipristal acetate versus leuprolide acetate for the treatment of symptomatic uterine fibroids before surgery.

**Outcomes**: Control of uterine bleeding at week 13 was the primary outcome. Secondary outcomes included bleeding pattern, amenorrhea, changes in fibroid/uterine volume, and global pain score.

**Patients**: 307 premenopausal women with symptomatic fibroids and excessive uterine bleeding were randomly assigned to oral ulipristal acetate (5 mg or 10 mg) or intramuscular injections of leuprolide acetate.

**Results**: Control of bleeding at week 13 was not significantly different between the treatment groups. All three treatments reduced uterine volume, although this decrease was significantly greater in the leuprolide group (47% reduction) than in the ulipristal groups (20-22%). 40% of the leuprolide group reported moderate-to-severe hot flashes, but only 17% (5 mg) and 10% (10 mg) of the ulipristal groups did.

**Conclusions**: Oral ulipristal acetate (5 mg or 10 mg) is noninferior to intramuscular leuprolide acetate for control of uterine bleeding due to fibroids, and it had a better side-effect profile.

**Suppression of Ovarian Activity with a Drosperone-Containing Oral Contraceptive in a 24/4 Regimen**

**Suppression of ovarian activity**: A 24/4 regimen is associated with greater ovarian suppression than the 21/7 regimen.

**Study**: Double-blind randomized.

**Patients**: Women aged 18-35 yr, post-ovulation or had a follicular diameter ≥15 mm before day 23 during a pre-treatment cycle.

**Intervention**: Drospirenone 3 mg plus ethinyl estradiol 20 µg administered in 24/4 regimen vs. 21/7 regimen.

**Outcome**: Suppression of ovarian activity (Hoogland score).

**Results**: Women on a 24/4 regimen had greater and more consistent ovarian suppression than the 21/7 group. More women in the 24/4 group had no ovarian activity compared to women in the 21/7 group.

**Conclusion**: A 24/4 regimen is associated with greater ovarian suppression than a 21/7 regimen.
Contraception

</tbody>
</table>

Effectiveness: percentage of women reporting no pregnancy after 1 yr of use.

Hormonal Methods

Combined Oral Contraceptive Pills (OCPs)
- most contain low dose ethinyl estradiol (20-35 μg) plus progestin (norethindrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone)
- failure rate (0.3% to 8%) depending on compliance
- monophasic or triphasic formulations (varying amount of progestin throughout cycle)

Transdermal (Ortho Evra®)
- continuous release of 6 mg norelgestromin and 0.60 mg ethinyl estradiol into bloodstream
- applied to lower abdomen, back, upper arm, buttocks, NOT breast
- worn for 3 consecutive weeks (changed every wk) with 1 wk off to allow for menstruation
- as effective as OCP in preventing pregnancy (>99% with perfect use)
- may be less effective in women >90 kg
- may not be covered by drug plans

Contraceptive Ring (Nuva Ring®)
- thin flexible plastic ring; releases etonogestrel 120 μg/d and estradiol 15 μg/d
- works for 3 wk then removed for 1 wk to allow for menstruation
- as effective as OCP in preventing pregnancy (98%)
- avoids first pass effect
- side effects: vaginal infections/irritation, vaginal discharge
- may have better cycle control; i.e. decreased breakthrough bleeding

Starting Hormonal Contraceptives
- thorough history and physical examination, including blood pressure and breast exam
- follow-up visit 6 wk after hormonal contraceptives prescribed
- pelvic exam can be delayed until a subsequent visit

Contraceptive Ring (Nuva Ring®)

Transdermal (Ortho Evra®)

Combined Oral Contraceptive Pills (OCPs)

Barrier Methods

Physiological

Withdrawal/cotus interruptus
Rhythm method/calendar/mucus/symptothermal
Lactational amenorrhea
Chance – no method used
Abstinence of all sexual activity

Barrier Methods

Condom alone
Spermicide alone
Sponge – Parous
– Nulliparous
Diaphragm with spermicide
Female condom
Cervical cap – Parous
– Nulliparous

Effectiveness: percentage of women reporting no pregnancy after 1 yr of use.

Cervical cap – Parous
Female condom
Diaphragm with spermicide
Sponge – Parous
Spermicide alone
Condom alone
Abstinence of all sexual activity

Hormonal

OCP
Nuva Ring®
Transdermal (Ortho Evra®)
Depo-Provera®
Progestin-only pill (Micronor®)
Minora® IUD

Emergency Postcoital Contraception (EPC)

“Yuzpe” method
“Plan B” levonorgestrel only
Postcoital IUD

Effect of ethinyl estradiol dose
ALL OCPs with ≤35 μg ethinyl estradiol carry a lower risk of VTE compared with oral contraceptives with 50 μg.

Effect of progestin type
Drospirenone: third generation progestin, e.g. Yasmin® and Yaz®
Levonorgestrel: second generation progestin, e.g. Alesse®

J Obstet Gyn Canada 2010;32:1192-1197

Rates of venous thromboembolism
(VTE: DVT and PE) expressed in women/yr
Non-users of reproductive age
4-5/10 000
Oral contraceptive (OCP) users
9-10/10 000
Pregnancy
29/10 000
Immediate post-partum
300-400/10 000
* Risk is highest in the first months of use and in medication switch.

Abstinence of all sexual activity
Condom alone
Spermicide alone
Diaphragm with spermicide
Female condom
Cervical cap – Parous
– Nulliparous

Counselling the Adolescent about Contraception

More than 90% of adolescent pregnancies are unintended, and ~50% of all pregnancies occur within the first 6 mos of initiating sexual activity. In addition, 85% of sexually active women become pregnant within 1 yr if no contraception is used and even some of the least effective contraceptive methods markedly decrease the risk of pregnancy.

Emergency Postcoital Contraception (EPC)

“Yuzpe” method
“Plan B” levonorgestrel only
Postcoital IUD

Effect of ethinyl estradiol dose
ALL OCPs with ≤35 μg ethinyl estradiol carry a lower risk of VTE compared with oral contraceptives with 50 μg.

Effect of progestin type
Drospirenone: third generation progestin, e.g. Yasmin® and Yaz®
Levonorgestrel: second generation progestin, e.g. Alesse®

Two high quality research studies found comparable VTE rates with drospirenone-containing OCPs and other approved products.
1. Dinger et al., Contraception 2007;75:344-354

Two reports with significant methodological flaws found increased VTE risk. Results and conclusions may have been distorted by residual confounding.
1. Liedgard et al., BMJ 2008;339:a2680
2. Van Hylckama Vlieg et al., BMJ 2009;339:b2890

Conclusion
Occurrence of serious risks, such as VTE, is rare with all contemporary OCPs.
Individualized risk assessment is mandatory.
For most healthy women of reproductive age, the benefits of OCPs will outweigh the risks.

Risk of Non-Fatal Venous Thromboembolism in Women Using Oral Contraceptives Containing Drospirenone Compared with Women Using Oral Contraceptives Containing Levonorgestrel: A Case-Control Study Using United States Claims Data
BMJ 2011;342:d2151

Study: Nested case-control and cohort study.
Patients: Women aged 15-44 yr receiving oral contraceptives
Intervention: Drospirenone-containing contraceptive vs. Levonorgestrel-containing contraceptive.
Outcome: Non-fatal venous thromboembolism.
Results: Women receiving drospirenone-containing oral contraceptives had twice as likely to develop non-fatal VTE compared to women receiving levonorgestrel-containing contraceptives (age-adjusted incidence rate ratio was 2.0).

Reference: World Health Organization Guidelines for Oral Contraceptive Use

Missed Combined OCPs

- Miss 1 pill in <24 h
  - Take 1 pill ASAP and the next pill at the usual time
- Miss ≥1 pill in a row in first wk
  - Take 1 pill ASAP and continue taking one pill daily until the end of the pack
  - Use back-up contraception for 7 d. EPC may be necessary
- Miss <3 pills in 2nd or 3rd wk of cycle
  - Take 1 pill ASAP and continue taking one pill daily until the end of the pack
  - Do not take placebo (28-d packs) or do not take a hormone free interval (21-d packs)
  - Start the next pack immediately after finishing the previous one
  - No need for back-up contraception

PROGESTIN-ONLY METHOD
Selected Examples of Progestin-Only Methods

Progestin-Only Pill ("minipill")
- Micronor® 0.35 mg norethindrone
- taken daily at same time of day to ensure reliable effect; no pill free interval
- higher failure rate (1.1-13% with typical use, 0.51% with perfect use) than other hormonal methods
- ovulation inhibited in 60% of women; most have regular cycles (but may cause oligo/amenorrhoea)
- highly effective if also post-partum breastfeeding, or if >3.5 yr

Depo-Provera®
- injectable depot medroxyprogesterone acetate
- dose 150 mg IM q12-14wk (convenient dosing)
- initiate within 5 d of beginning of normal menses, immediately postpartum in breastfeeding women
- irregular spotting progresses to complete amenorrhea in 70% of women (after 1-2 yr of use)
- highly effective 99%; failure rate 0.3%
- side effect: decreased bone density (may be reversible)
- disadvantage: restoration of fertility may take up to 1-2 yr

Intrauterine Device (IUD)

Table 11. IUD Contraceptive Methods

<table>
<thead>
<tr>
<th>Mechanism of Action</th>
<th>Side Effects</th>
<th>Contraindications</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Copper-containing IUD (Nova-T®): mild foreign body reaction in endometrium toxic to sperm and alters sperm motility</td>
<td>• Both Copper and Progesterone IUD</td>
<td>• Both Copper and Progesterone IUD</td>
</tr>
<tr>
<td>• Progestrone-releasing IUD (Mirena®): decidualization of endometrium and thickening of cervical mucus; minimal effect on ovulation</td>
<td>• Breakthrough bleeding</td>
<td>• Known or suspected pregnancy</td>
</tr>
<tr>
<td>• Highly effective (95-99%); failure rate 0-1.2%</td>
<td>• Expulsion (5% in the first year, greatest in first month and in nulliparous women)</td>
<td>• Undiagnosed genital tract bleeding</td>
</tr>
<tr>
<td>• Contraceptive effects last 5 yr</td>
<td>• Uterine wall perforation (1/1000) on insertion</td>
<td>• Acute or chronic PID</td>
</tr>
<tr>
<td>• Reversible, private, convenient</td>
<td>• If pregnancy occurs with an IUD, increased risk of ectopic</td>
<td>• Lifestyle risk for STIs*</td>
</tr>
<tr>
<td>• May be used in women with contraindications to OCPs or wanting long-term contraception</td>
<td>• Increased risk of PID (within first 10 d of insertion only)</td>
<td>• Copper IUD:</td>
</tr>
<tr>
<td></td>
<td>• Copper IUD: increased blood loss and duration of menses, dysmenorrhea</td>
<td>• Known allergy to copper</td>

</tbody>
</table>

* Cervical swabs for gonorrhea and chlamydia should be done prior to IUD insertion.

Assessing the Risk of Venous Thromboembolic Events in Women Taking Progestin-Only Contraception: A Meta-Analysis
BMJ 2012;345:e4944
Published online 2012 August 7. doi: 10.1136/ bmj.e4944
Study: Systematic review and meta-analysis of RCTs and observational studies to see if there is an increased risk of VTE on progestin only OCP and if route of administration had any effect.
Results: They found 9 observational studies. Across all 8 studies, 167 women had VTEs. The adjusted relative risk of a VTE for users versus non-users of a progestin-only contraceptive was 1.03 (95% CI 0.76 to 1.39).
Conclusion: Oral and intracervical route made no difference. The relative risk of a VTE for users of an injectable progestin versus non-users was 2.67 (1.29 to 5.53).

New SOGC Recommendations for Depo-Provera® Users
- Inform patients of potential risks and benefits at intervals throughout course of treatment
- Recommend ways to improve bone health such as calcium, vitamin D, weight-bearing exercise, smoking cessation, decreased alcohol and caffeine intake
- There is no evidence to suggest routine BMD testing

Missed Progestin-Only Pills > 3 hours
Use back-up contraceptive method for at least 48 h. Continue to take remainder of pills as prescribed.

Missed Depo-Provera
- If last injection given 13-14 wk prior: give next injection immediately
- If > 14 wk prior, do β-hCG:
  - If β-hCG is positive, give EPC and no injection
  - If β-hCG is negative, give next injection right away and:
    - Intercourse occurred in last 5 d: give EPC, use back-up contraception for 7 d. Repeat β-hCG in 3 wk
    - Intercourse occurred > 5 d ago but within the last 14 d: use back-up contraception for 7 d. Repeat β-hCG in 3 wk
    - Intercourse occurred > 14 d ago: use back-up contraception for 7 d
- No evidence of fetal abnormalities if conceived on DMPA

Medroxyprogesterone (Depo-Provera®) and Bone Mineral Density Loss
CMAJ 2005;172:174
Extended use (up to 5 yr) of medroxyprogesterone acetate has been found to decrease spine and hip bone mineral density (BMD) by 4% to 6.9%. 2 yr after discontinuation, only partial recovery of BMD has been noted.

Canadian Consensus Guideline on Continuous and Extended Hormonal Contraception
J Obstet Gyn Canada 2007;29:S1-32
Definitions
- Extended Use: The use of combined hormonal contraceptives without hormone-free intervals.
- Continuous Use: Uninterrupted use of combined hormonal contraceptives without hormone-free intervals.

What can be used?
Oral, transdermal and vaginally administered combined hormonal contraceptives, including those originally designed for cyclic use, can be administered in a variety of Continuous and Extended (CE) regimens.

Efficacy and Adherence
Continuous combined hormonal contraceptive regimes are as effective as cyclic regimes in preventing pregnancy. Use of CE combined hormonal contraceptives may be more “forgiving” about missed doses because of the absence of a hormone-free interval.

Side Effects
The side effect profile of CE combined hormonal contraceptive regimes is not worse than with cyclic regimes, and may even be improved.

Medical/Non-contraceptive Use
For women in the perimenopausal transition who may be ovulating, CE combined hormonal contraceptive is preferred to hormonal replacement therapy for controlling problematic bleeding and vasomotor symptoms.
Emergency Postcoital Contraception (EPC)

</tbody>
</table>

Follow-up
- 3-4 wk post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
- contraception counseling

Infertility

Epidemiology
- 10-15% of couples
- must investigate both members of the couple

Female Factors

Etiology
- ovulatory dysfunction (15-20%)
  - hypotalamic (hypothalamic amenorrhea)
  - pituitary (prolactinoma, hypopituitarism)
  - ovarian
    - PCOS
    - premature ovarian failure
    - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone), poorly understood
- systemic diseases (thyroid, Cushing’s syndrome, renal/hepatic failure)
- congenital (Turner’s syndrome, gonadal dysgenesis or gonadotropin deficiency)
- stress, poor nutrition, excessive exercise (even with presence of menstruation)

- outflow tract abnormality (15-20%)
  - tubal factors (20-30%)
    - PID
  - adhesions (previous surgery, peritonitis, endometriosis)
  - ligation/occlusion (e.g. previous ectopic pregnancy)
  - uterine factors (<5%)
    - congenital anomalies, bicornuate uterus, septate uterus, prenatal DES exposure
  - intrauterine adhesions (e.g. Asherman's syndrome)
  - infection (endometritis, pelvic TB)
  - fibroids/polyps (particularly intrauterine)
  - endometrial ablation
  - cervical factors (5%)
    - hostile or acidic cervical mucus
    - anti-sperm antibodies
    - structural defects (cone biopsies, laser or cryotherapy)
• endometriosis (15-30%)
• multiple factors (30%), see GY22
• unknown factors (10-15%)

**Investigations**

- **ovulatory**
  - day 3: FSH, LH, TSH, prolactin ± DHEA, free testosterone (if hirsute)
  - day 21-23: serum progesterone to confirm ovulation
  - initiate basal body temperature monitoring (biphasic pattern)
  - postcoital test: evaluate mucus for clarity, pH, spinnbarkeit/fibrosity (rarely done)
- **tubal factors**
  - HSG (can be therapeutic – opens fallopian tube)
  - SHG (can be therapeutic – opens fallopian tube)
  - laparoscopy with dye insufflation (or tubal dye test)
- **peritoneal/uterine factors**
  - HSG/SHG, hysteroscopy
- **other**
  - karyotype

**Treatment**

- education: timing of intercourse in relation to ovulation (from 2 d prior to 2 d following presumed ovulation), every other day
- **medical**
  - ovulation induction
    - clomiphene citrate (Clomid®): estrogen antagonist that causes a perceived decreased estrogen state, resulting in increased pituitary gonadotropins; causes increased FSH and LH, leading to ovulation induction (works much better if anovulatory)
    - human menopausal gonadotropin – HMG (Pergonal®), urofollitropin – FSH (Metrodin®)
      - FSH and LH extracted from urine of postmenopausal women
      - followed by β-hCG for stimulation of ovum release
    - may add
      - bromocriptine (dopamine agonist) if elevated prolactin
      - dexamethasone for hyperandrogenism (adult onset congenital adrenal hyperplasia)
      - metformin (for PCOS)
      - luteal phase progestrone supplementation for luteal phase defect (mechanism not completely understood)
      - ASA (81 mg PO OD) for women with a history of recurrent spontaneous abortions (for antiphospholipid antibody syndrome)
- **surgical/procedural**
  - tubuloplasty
  - lysis of adhesions
  - artificial insemination: intracervical insemination (ICI), intrauterine insemination (IUI), intrauterine tuboperitoneal insemination (IUTPI), intratubal insemination (ITI)
  - sperm washing
  - IVF (in vitro fertilization)
  - IFF (intrafallopian transfer)
  - GIFT* (gamete intrafallopian transfer): immediate transfer with sperm after oocyte retrieval
  - ZIFT* (zygote intrafallopian transfer): transfer after 24 h culture of oocyte and sperm
  - TET* (tubal embryo transfer): transfer after >24 h culture
  - ICSI (intracytoplasmic sperm injection)
  - IVM (in vitro maturation)
  - ± oocyte or sperm donors
  - ± pre-genetic screening for single gene defects in karyotype of zygote
  - *Not performed in Canada

### Male Factors

- see Urology, U33

**Etiology**

- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)

**Investigations**

- semen analysis and culture
- post-coital (Hühner) test: rarely done

---

**When Should Investigations Begin?**

- <35 yr: after 1 yr of unprotected intercourse
- 35-40 yr: after >6 mo
- >40 yr: immediately

**Earlier if:**

- History of PID
- History of infertility in previous relationship
- Prior pelvic surgery
- Chemotherapy/radiation in either partner
- Recurrent pregnancy loss
- Moderate-severe endometriosis

**Controversial and Evolving Ethical Issues**

- Infertility demands non-judgmental discussion
- Ethical issues surrounding therapeutic donor insemination in same sex couples, surrogacy, donor gametes and other advanced reproductive technologies are still evolving and remain controversial
- If the doctor finds that certain treatment options lie outside of their moral boundaries, the infertile couple should be referred to another physician

**Summary of Current Legislation in Canada**

**Bill C-13 Assisted Human Reproduction Act 2004:**

- **What is allowed**
  - Cloning people
  - Cloning stem cells
  - Growing human embryos for research
  - Sex selection
  - Making changes to human DNA that would pass from one generation to the rest
  - Creating people who have animal DNA
  - Buying or selling embryos, sperm, eggs or other human reproductive material
- **What is not allowed**
  - Surrogate mothers
  - Donating sperm, eggs and other reproductive material
  - Using embryos, sperm, eggs, etc., to assist conception
  - Using human embryos and stem cells in research
  - Sex selection in X-linked genetic diseases

**Normal Semen Analysis (WHO lower reference limits)**

- Must be obtained after 2-7 d of abstinence
- **Volume** 1.5 cc
- **Count** 15 million/cc
- **Motility** 58% live
- **Motility** 32% progressive, 40% total (progressive + non-progressive)
- **Morphology** 4.0% normal
Gynecological Infections

Physiologic Discharge

- clear, white, flocculent, odourless discharge; pH 3.8-4.2
- smear contains epithelial cells, Lactobacilli
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

Vulvovaginitis

PREPUBERTAL VULVOVAGINITIS

- clinical features
  - irritation, pruritus
  - discharge
  - vulvar erythema
  - vaginal bleeding (specifically due to Group A Streptococci and Shigella)
- differential diagnosis
  - non-specific vulvovaginitis (25-75%)
  - infections (respiratory, enteric, systemic, sexually acquired)
  - foreign body (toilet paper most common)
  - Candida (if using diapers)
  - pinworms
  - polyps, tumour (ovarian malignancy)
  - vulvar skin disease (lichen sclerosis, condyloma acuminata)
  - trauma (accidental straddle injury, sexual abuse)
  - psychosomatic vaginal complaints (specific to vaginal discharge)
  - endocrine abnormalities (specific to vaginal bleeding)
  - blood dyscrasia (specific to vaginal bleeding)
- etiology
  - infectious:
    - poor hygiene, proximity of vagina to anus
    - recent infection (respiratory, enteric, systemic)
    - STI: investigate sexual abuse
  - nonspecific:
    - lack of protective hair and labial fat pads
    - lack of estrogenization
    - susceptible to chemicals, soaps (bubble baths), medications and clothing
    - enuresis
- investigations
  - vaginal swab for culture (specifically state that it is a pre-pubertal specimen)
- treatment
  - enhanced hygiene and local measures (handwashing, white cotton underwear, no nylon tights, no tight fitting clothes, no sleeper pajamas, sitz baths, avoid bubble baths, use mild detergent, eliminate fabric softener, avoid prolonged exposure to wet bathing suits, urination with legs spread apart)
  - A&D® dermatological ointment (vitamin A/D) to protect vulvar skin
  - infectious: treat with antibiotics for organism identified

Table 13. Other Common Causes of Vulvovaginitis in Prepubertal Girls

<table>
<thead>
<tr>
<th>Pinworms</th>
<th>Lichen Sclerosis</th>
<th>Foreign Body</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diagnosis</td>
<td>Collophane tape test</td>
<td>Area of white patches and thinning of skin</td>
</tr>
<tr>
<td>Treatment</td>
<td>Empirical treatment with mebendazole</td>
<td>Topical steroid creams</td>
</tr>
</tbody>
</table>

Most common gynecological problem in prepubertal girls is non-specific vulvovaginitis, not yeast!

There is no high quality evidence showing a link between vulvovaginal candidiasis and hygienic habits or wearing tight or synthetic clothing.

Prepubertal and Adolescent Gynecological Infections: Legal Aspects of Confidentiality

- Clinicians who treat adolescents must be aware of federal, state and provincial laws related to adolescent consent and confidentiality
- They must be aware of guidelines governing funding sources for particular services and be familiar with the consent and confidentiality policies of the facility in which they practice
POSTMENOPAUSAL VAGINITIS/ATROPHIC VAGINITIS

- clinical features
  - dyspareunia
  - post-coital spotting
  - mild pruritus
- investigations
  - atrophy is usually a visual diagnosis: thinning of tissues, erythema, petechiae, bleeding points, dryness on speculum exam
  - rule out malignancy: especially endometrial cancer
- treatment
  - local estrogen replacement (ideal): Premarin® cream, VagiFem® tablets, or Estring®
  - oral or transdermal hormone replacement therapy (if treatment for systemic symptoms is desired)
  - good hygiene

INFECTIOUS VULVOVAGINITIS

</table>
Sexually Transmitted Infections (STIs)

- see Family Medicine, FM46

TRICHOMONIASIS
- see Infectious Vulvovaginitis, Table 14, GY25

CHLAMYDIA

Etiology
- Chlamydia trachomatis

Epidemiology
- most common bacterial STI in Canada
- often associated with N. gonorrhoeae

Clinical Features
- asymptomatic (80% of women)
- muco-purulent endocervical discharge
- urethral syndrome: dysuria, frequency, pyuria, no bacteria on culture
- pelvic pain
- post-coital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
- symptomatic sexual partner

Investigations
- cervical culture or nucleic acid amplification test
- obligate intracellular parasite: tissue culture is the definitive standard
- urine and vaginal tests now available, which are equally or more effective than cervical culture

Treatment
- doxycycline 100 mg PO bid for 7d or azithromycin 1 g PO in a single dose (may use in pregnancy)
- also treat gonorrhea because of high rate of co-infection
- treat partners
- reportable disease
- test of cure for chlamydia required in pregnancy (cure rates lower in pregnant patients) → retest 3-4 wk after initiation of therapy

Screening
- high risk groups
- during pregnancy
- with initiation of OCP (independent risk factor)
Complications
• acute salpingitis, PID
• Fitz-Hugh-Curtis syndrome (liver capsule inflammation)
• reactive arthritis (male predominance; HLA-B27 associated), conjunctivitis, urethritis
• infertility; tubal obstruction from low grade salpingitis
• ectopic pregnancy
• chronic pelvic pain
• perinatal infection: conjunctivitis, pneumonia

GONORRHEA
Etiology
• Neisseria gonorrhoeae
• symptoms and risk factors same as with chlamydia

Investigations
• Gram stain shows Gram-negative intracellular diplococci
• cervical, rectal and throat culture (if clinically indicated)

Treatment
• single dose of ceftriaxone 250 mg IM, or cefixime 800 mg PO
• if pregnant: above regimen or 2 g spectinomycin IM (avoid quinolones)
• also treat chlamydia, because of high rate of co-infection
• treat partners
• reportable disease
• screening as with Chlamydia

HUMAN PAPILLOMAVIRUS (HPV)
Etiology
• most common viral STI in Canada
• >200 subtypes, of which >30 are genital subtypes
• HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
• HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
• types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma

Clinical Features
• latent infection
  • no visible lesions, asymptomatic
  • only detected by DNA hybridization tests
• subclinical infection
  • visible lesion found during colposcopy or on Pap test
• clinical infection
  • visible wart-like lesion without magnification
  • hyperkeratotic, verrucous or flat, macular lesions
  • vulvar edema

Investigations
• cytology (see Cervical Screening Pap Test, GY43)
  • koilocytosis: nuclear enlargement and atypia with perinuclear halo
• biopsy of lesions at colposcopy
• detection of HPV DNA subtype using nucleic acid probes (not routinely done but can be done in presence of abnormal Pap test to guide treatment)

Treatment
• patient administered:
  • podofilox 0.5% solution or gel bid x 3 d in a row (4 d off) then repeat x 4 wk
  • imiquimod (Aldara®) 5% cream 3x/wk qhs x 16 wk
• provider administered:
  • cryotherapy with liquid nitrogen: repeat q1-2wk
  • podophyllin resin in tincture of benzoin: weekly
  • trichloroacetic acid (TCA) or bichloroacetic acid weekly (80-90%); safe in pregnancy
  • surgical removal/laser
  • intralesional interferon

Prevention
• vaccination: Gardasil®, Cervarix® see Table 25, GY44
• condoms may not fully protect (areas not covered, must be used every time throughout entire sexual act)
HERPES SIMPLEX VIRUS (HSV) OF VULVA

Etiology
- 90% are HSV-2, 10% are HSV-1

Clinical Features
- may be asymptomatic
- initial symptoms: present 2-21 d following contact
- prodromal symptoms: tingling, burning, pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 d after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: less severe, less frequent and shorter in duration (especially with HSV-1)

Investigations
- viral culture preferred in patients with ulcer present, however decreased sensitivity as lesions heal
- cytologic smear (Tzanck smear)
  - multinucleated giant cells, acidophilic intranuclear inclusion bodies
- type specific serologic tests for antibodies to HSV-1 and HSV-2 (not available routinely in Canada)
- HSV DNA PCR

Treatment
- first episode
  - acyclovir 400 mg PO tid x 7-10 d, or famciclovir 250 mg PO tid x 7-10 d, or valacyclovir 1 g PO bid x 7-10 d
- recurrent episode
  - acyclovir 400 mg PO tid x 3-5 d, or famciclovir 125 mg PO bid x 3-5 d, or valacyclovir 500 mg PO bid x 3 d
- daily suppressive therapy
  - consider if 6-8 recurrences per year
  - acyclovir 400 mg PO bid, or famciclovir 250 mg bid, or valacyclovir 0.5-1 g PO OD
- severe disease
  - consider IV therapy acyclovir 5-10 mg/kg IV q8h x 5-7 d
- education regarding transmission
- avoid contact from onset of prodrome until lesions have cleared
- use barrier contraception

SYPHILIS

Etiology
- Treponema pallidum

Classifications
- primary syphilis
  - 3-4 wk after exposure
  - painless chancre on vulva, vagina or cervix
  - painless inguinal lymphadenopathy
  - serological tests usually negative, local infection only
- secondary syphilis (can resolve spontaneously)
  - 2-6 mo after initial infection
  - nonspecific symptoms: malaise, anorexia, headache, diffuse lymphadenopathy
  - generalized maculopapular rash: palms, soles, trunk, limbs
  - condylomata lata: anogenital, broad-based fleshy grey lesions
  - serological tests usually positive
- latent syphilis
  - no clinical manifestations; detected by serology only
- tertiary syphilis
  - may involve any organ system
  - neurological: tabes dorsalis, general paresis
  - cardiovascular: aortic aneurysm, dilated aortic root
  - vulvar gumma: nodules that enlarge, ulcerate and become necrotic (rare)
- congenital syphilis
  - may cause fetal anomalies, stillbirths or neonatal death
Investigations
- aspiration of ulcer serum or node
- darkfield microscopy (most sensitive and specific diagnostic test for syphilis)
  - spirochetes
- non-treponemal screening tests (VDRL, RPR); nonreactive after treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
  - confirmatory tests; remain reactive for life (even after adequate treatment)

Treatment
- treatment of primary, secondary, latent syphilis of <1 yr duration
  - benzathine penicillin G 2.4 million units IM single dose
  - treat partners, reportable disease
- treatment of latent syphilis >1 yr duration
  - benzathine penicillin G 2.4 million units IM q1wk x 3 wk
- treatment of neurosyphilis
  - IV aqueous penicillin G 3-4 million units IM q4h x 10-14 d
- screening
  - high risk groups
  - in pregnancy (see Obstetrics, Table 13, OB21)

Complications
- if untreated, 1/3 will experience late complications

HIV
- see Infectious Diseases, ID41

Bartholinitis/Bartholin Gland Abscess
Etiology
- often anaerobic and polymicrobial
  - U. urealyticum, N. gonorrhoeae, C. trachomatis, E. coli, P. mirabilis, Streptococcus spp., S. aureus (rare)
  - blockage of duct
Clinical Features
- unilateral swelling and pain in inferior lateral opening of vagina
  - sitting and walking may become difficult and/or painful
Treatment
- sitz baths, warm compresses
  - antibiotics: cephalaxin x 1 wk
  - incision and drainage using local anesthesia with placement of Word catheter (10 French latex catheter) for 2-3 wk
  - marsupialization under general anesthetic – more definitive treatment
  - rarely treated by removing gland

Pelvic Inflammatory Disease (PID)
- up to 20% of all gynecology-related hospital admissions

Etiology
- causative organisms (in order of frequency)
  - C. trachomatis
  - N. gonorrhoeae
  - gonorrhea and chlamydia often co-exist
  - endogenous flora: anaerobic, aerobic, or both
    - E. coli, Staphylococcus, Streptococcus, Enterococcus, Bacteroides, Peptostreptococcus, H. influenzae, G. vaginalis
  - cause of recurrent PID
  - associated with instrumentation
  - Actinomyces israelii (Gram-positive, non acid-fast anaerobe)
  - 1-4% of PID cases associated with IUDs
  - others (TB, Gram-negatives, CMV, U. urealyticum, etc.)

Risk Factors
- age <30 yr
- risk factors as for chlamydia and gonorrhea
  - vaginal douching
  - IUD (within first 10 d after insertion)
  - invasive gynecologic procedures (D&C, endometrial biopsy)
**Clinical Presentation**
- up to 2/3 asymptomatic: many subtle or mild symptoms
- common
  - fever >38.3°C
  - lower abdominal pain and tenderness
  - abnormal discharge: cervical or vaginal
- uncommon
  - nausea and vomiting
  - dysuria
  - AUB
- chronic disease (often due to chlamydia)
  - constant pelvic pain
  - dyspareunia
  - palpable mass
  - very difficult to treat, may require surgery

**Investigations**
- bloodwork
  - β-hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine R&M
- speculum exam, bimanual exam
  - vaginal swab for Gram stain, C&S
  - cervical cultures for *N. gonorrhoea, C. trachomatis*
  - endometrial biopsy will give definitive diagnosis (rarely done)
- ultrasound
  - may be normal
  - free fluid in cul-de-sac
  - pelvic or tubo-ovarian abscess
  - hydrosalpinx (dilated fallopian tube)
- laparoscopy (gold standard)
  - for definitive diagnosis: may miss subtle inflammation of tubes or endometritis

**Treatment**
- must treat with polymicrobial coverage
- inpatient if:
  - moderate to severe illness
  - atypical infection
  - adnexal mass, tubo-ovarian or pelvic abscess
  - unable to tolerate oral antibiotics or failed oral therapy
  - immunocompromised
  - pregnant
  - adolescent – first episode
  - surgical emergency cannot be excluded (e.g. ovarian torsion)
  - PID is secondary to instrumentation
- recommended treatment
  - cefoxitin 2 g IV q6h (no longer available in U.S.A.) or cefotetan 2 g IV q12h + doxycycline 100 mg IV/PO q12h or
  - clindamycin 900 mg IV q8h + gentamicin 2 mg/kg IV loading dose then gentamicin 1.5 mg/kg q8h maintenance dose
  - continue IV antibiotics for 24 h after symptoms have improved then doxycycline 100 mg PO bid to complete 14 d
  - percutaneous drainage of abscess under U/S guidance
  - when no response to treatment, laparoscopic drainage
  - if failure, treatment is surgical (salpingectomy, TAH/BSO)
- outpatient if:
  - typical findings
  - mild to moderate illness
  - oral antibiotics tolerated
  - compliance ensured
  - follow-up within 48-72 h (to ensure symptoms not worsening)
- recommended treatment:
  - ofloxacin 400 mg PO bid x 14 d or levofloxacin 500 mg PO bid x 14 d ± metronidazole 500 mg PO bid x 14 d (if suspect abscess)
  - ceftriaxone 250 mg IM x 1 + doxycycline 100 mg PO bid x 14 d or cefoxitin 2 g IM x 1 + probenecid 1 g PO + doxycycline 100 mg PO bid ± metronidazole 500 mg PO bid x 14 d
  - consider removing IUD after a minimum of 24 h of treatment
  - reportable disease
  - treat partners
  - consider re-testing for *C. trachomatis* and *N. gonorrhoea* 4-6 wk after treatment if documented infection

---

**PID Complications**
**FACE PID**
- *Infertility*
- *Fitz-Hugh-Curtis syndrome*
- *Abscesses*
- *Chronic pelvic pain*
- *Ectopic pregnancy*
- *Peritonitis*
- *Intestinal obstruction*
- *Disseminated infection* (sepsis, endocarditis, arthritis, meningitis)

**PID Diagnosis**
- **Must have:**
  - Lower abdominal pain
- **Plus one of:**
  - Cervical motion tenderness
  - Adnexal tenderness
- **Plus one or more of:**
  - High risk partner
  - Temperature >38°C
  - Mucopurulent cervical discharge
  - Positive culture for *N. gonorrhoea, C. trachomatis, E. coli, or other vaginal flora*
  - Cul-de-sac fluid, pelvic abscess or inflammatory mass on U/S or bimanual
  - Leukocytosis
  - Elevated ESR or CRP (not commonly used)

**Alternative PID Treatments**
For patients with contraindications to treatment with cephalosporins or quinolones, recent evidence suggests that a short course of azithromycin at a dose of either 250 mg PO daily for 1 wk or 1 g PO weekly for 2 wk combined with metronidazole is effective in achieving a clinical cure for acute PID.

**Source:** Update to the Canadian Guidelines on Sexually Transmitted Infections. January 2010.
Complications of Untreated PID

- chronic pelvic pain
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
  - 1 episode of PID → 13% infertility
  - 2 episodes of PID → 36% infertility
- bacteremia
- septic arthritis, endocarditis

Toxic Shock Syndrome

- see Infectious Diseases, ID26

Risk Factors

- tampon use
- diaphragm, cervical cap or sponge use (prolonged use, i.e. >24 h)
- wound infections
- post-partum infections
- early recognition and treatment of syndrome is imperative as incorrect diagnosis can be fatal

Clinical Presentation

- sudden high fever
- sore throat, headache, diarrhea
- erythroderma
- signs of multisystem organ failure
- refractory hypotension
- exfoliation of palmar and plantar surfaces of the hands and feet 1-2 wk after onset of illness

Treatment

- remove potential sources of infection (foreign objects and wound debris)
- debride necrotic tissues
- adequate hydration
- penicillinase-resistant antibiotics, e.g. cloxacillin
- steroid use controversial but if started within 72 h, may reduce severity of symptoms and duration of fever

Surgical Infections

Post-Operative Infections in Gynecological Surgery

- pelvic cellulitis
  - common post hysterectomy, affects vaginal vault
  - erythema, induration, tenderness, discharge involving vaginal cuff
  - treat if fever and leukocytosis with broad spectrum antibiotics, i.e. clindamycin and gentamicin
  - drain if excessive purulence or large mass
  - can result in intra-abdominal and pelvic abscess
- see General Surgery, Post-Operative Fever, GS7

Sexual Abuse

- see Family Medicine, FM28, Emergency Medicine, ER29

Sexuality and Sexual Dysfunction

SEXUAL RESPONSE

1. desire: energy that allows an individual to initiate or respond to sexual stimulation
2. arousal: physical and emotional stimulation leading to breast and genital vasodilatation and clitoral engorgement
3. orgasm: physical and emotional stimulation is maximized, allowing the individual to relinquish their sense of control
4. resolution: most of the congestion and tension resolves within seconds, complete resolution may take up to 60 min

SEXUAL DYSFUNCTION

Etiology

- intrapsychic: patient's life experiences, value system
- relationship/interpersonal issues
- physical/organic
**Classification**
- lack of desire (60-70% of women)
- lack of arousal
- anorgasmia (5-10%)
  - primary anorgasmia: never before achieved orgasm under any circumstances
  - secondary anorgasmia: was able to achieve orgasms before but now unable to
- dyspareunia (3-6%): painful intercourse, superficial or deep
  - vaginismus (15%)
  - vulvodynia
  - vaginal atrophy
  - vulvar vestibulitis: associated with history of frequent yeast infections
  - PID

**Treatment**
- lack of desire: assess factors, rule out organic causes, relationship therapy, sensate focus exercises
- anorgasmia: self-exploration/pleasuring, relationship therapy if needed, bridging techniques (different sexual positions, clitoral stimulation during intercourse)
- dyspareunia
  - Kegel and reverse Kegel exercises
  - dilator treatment
  - comfort with self-exam
  - psychotherapy, other behavioural techniques
  - female on top position: allows for control of speed and duration
  - vestibulitis: remove local irritants, change in contraceptive methods, and dietary changes (increased citrate, decreased oxalate), vestibulectomy (rare)
  - vulvodynia: local moisturization, cold compresses, systemic nerve blocking therapy (amitriptyline, gabapentin), topical anesthetics, estrogen cream
  - pain clinic

**Menopause**
- see Family Medicine, FM42

**Definitions**
- lack of menses for 1 yr
- types of menopause
  - physiological; average age 51 yr (follicular atresia)
  - premature ovarian failure; before age 40 (autoimmune disorder, infection, Turner’s syndrome)
  - iatrogenic (surgical/radiation/chemotherapy)

**Clinical Features**
- associated with estrogen deficiency
  - vasomotor instability (tends to dissipate with time)
    - hot flushes/flashes, night sweats, sleep disturbances, formication, nausea, palpitations
  - urogenital atrophy involving vagina, urethra, bladder
    - dyspareunia, pruritus, vaginal dryness, bleeding, urinary frequency, urgency, incontinence
  - skeletal
    - osteoporosis, joint and muscle pain, back pain
  - skin and soft tissue
    - decreased breast size, skin thinning/loss of elasticity
  - psychological
    - mood disturbance, irritability, fatigue, decreased libido, memory loss

**Investigations**
- increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH). But FSH level not always predictive due to monthly variation. Use absence of menses for 1 yr to diagnose
- decreased levels of estradiol (later)

**Treatment**
- goal is for individual symptom management
  - vasomotor instability
    - HRT (first line), SSRI, venlafaxine, gabapentin, propranolol, clonidine
    - acupuncture
  - vaginal atrophy
    - local estrogen: cream (Premarin®), vaginal suppository (VagiFem®), ring (Estring®)
    - lubricants (Replens®)
  - urogenital health
    - lifestyle changes (weight loss, bladder re-training), local estrogen replacement, surgery

**Menopause Definitions**
- Occurrence of last spontaneous menstrual period, resulting from loss of ovarian function (loss of oocyte response to gonadotropins).
  - "Being in menopause" Lack of menses for 1 yr.
- Perimenopause
  - Period of time surrounding menopause (2-8 yr preceding + 1 yr after last menses) characterized by fluctuating hormone levels, irregular menstrual cycles, and symptom onset.

**Menopause Investigations**
- 85% of women experience hot flashes
- 20-30% seek medical attention
- 10% are unable to work
- Osteoporosis is the single most important health hazard associated with menopause
- Cardiovascular disease is the leading cause of death post-menopause
- Increased risk of breast cancer (RR 1.3) is associated with estrogen + progesterone HRT, but not with estrogen-only HRT
- All women taking HRT should have periodic surveillance and counseling regarding its benefits and risks
osteoporosis
- 1000-1500 mg calcium OD, 800-1000 IU vitamin D, weight-bearing exercise, quit smoking
- bisphosphonates (e.g. alendronate)
- selective estrogen receptor modifiers (SERMs): raloxifene (Evista®) – mimics estrogen effects on bone, avoids estrogen-like action on breast and uterine cancer; does not help hot flashes
- HRT: second-line treatment (unless for vasomotor instability as well)
- decreased libido
- vaginal lubrication, counseling, androgen replacement (testosterone cream or the oral form Andriol®)
- cardiovascular disease
- management of cardiovascular risk factors
- mood and memory
- antidepressants (first line), HRT (augments effect)
- alternative choices (not evidence-based, safety not established)
  - black cohosh, phytoestrogens, St. John's wort, gingko biloba, valerian, evening primrose oil, ginseng, Don Quai

Hormone Replacement Therapy (HRT)

- see Family Medicine, FM42
- primary indication is treatment of menopausal symptoms (vasomotor instability)
- keep doses low (e.g. 0.3 mg Premarin®) and duration of treatment short (<5 yr)

**HRT Components**

- estrogen
  - oral or transdermal (e.g. patch, gel)
  - transdermal preferred for women with hypertriglyceridemia or impaired hepatic function, smokers and women who suffer from headaches associated with oral HRT
  - low-dose (preferred dose: 0.3 mg Premarin®/25 µg Estradot® patch, can increase if necessary)
- progestin
  - given in combination with estrogen for women with an intact uterus to prevent development of endometrial hyperplasia/cancer

**Table 15. Examples of HRT Regimens**

<table>
<thead>
<tr>
<th>HRT Regimen</th>
<th>Estrogen Dose</th>
<th>Progestin Dose</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unopposed Estrogen</td>
<td>CEE 0.625 mg PO OD</td>
<td>None</td>
<td>If no intact uterus</td>
</tr>
<tr>
<td>Standard-dose</td>
<td>CEE 0.625 mg PO OD</td>
<td>MPA 2.5 mg PO OD or micronized progestrone 100 mg PO OD</td>
<td>Withdrawal bleeding may occur in a spotty, unpredictable manner. Usually abates after 6-8 mo due to endometrial atrophy. Once patient has become amenorrheic on HRT, significant subsequent bleeding episodes require evaluation (endometrial biopsy)</td>
</tr>
<tr>
<td>Standard-dose Cyclic</td>
<td>CEE 0.625 mg PO OD</td>
<td>MPA 5-10 mg PO days 1-14 only or micronized progestrone 200 mg PO OD days 1-14 only</td>
<td>Bleeding occurs monthly after day 14 of progestin. Can continue for years. PMS-like symptoms (breast tenderness, fluid retention, headache, nausea) are more prominent with cyclic HRT</td>
</tr>
<tr>
<td>Pulsatile</td>
<td>CEE 0.625 mg PO OD</td>
<td>MPA low-dose</td>
<td>3 d on, 3 d off</td>
</tr>
<tr>
<td>Transdermal</td>
<td>Estroderm®-Estradiol 0.05 mg/d or 0.1 mg/d</td>
<td>Estroderm®-MPA 2.5 mg PO OD</td>
<td>Use patch twice weekly. Can use oral progestins (Estroderm®)</td>
</tr>
<tr>
<td></td>
<td>Estalis®-Estradiol 140 µg/d or 250 µg/d</td>
<td>Estalis®-NEA 50 µg/d</td>
<td>Combined patches available (Estalis®)</td>
</tr>
</tbody>
</table>

CEE = conjugated equine estrogen (e.g. Premarin®); MPA = medroxyprogesterone acetate (e.g. Provera®); NEA = norethindrone acetate
Consider lower dose regimens, PREMPRO® 0.45/1.5 (Premarin® 0.45 mg and Provera® 1.5 mg)

**Side Effects of HRT**

- abnormal uterine bleeding
- mastodynia – breast tenderness
- edema, bloating, heartburn, nausea
- mood changes (progesterone)
- can be worse in progestrone phase of combined therapy

**Contraindications to HRT**

- absolute
  - acute liver disease
  - undiagnosed vaginal bleeding
  - known or suspected uterine cancer/breast cancer
  - acute vascular thrombosis or history of severe thrombophlebitis or thromboembolic disease
  - cardiovascular disease

Menopause Pathophysiology

- Degenerating theca cells fail to react to endogenous gonadotropins (FSH, LH)
- Less estrogen is produced
- Decreased negative feedback on hypothalamic-pituitary-adrenal axis
- Increased FSH and LH
- Stromal cells continue to produce androgens as a result of increased LH stimulation

Absolute Contraindications to HRT

ABCD
- Acute liver disease
- Undiagnosed vaginal bleeding
- Cancer (breast/uterine, Cardiovascular disease)
- DVT (thromboembolic disease)
• relative
  ▪ pre-existing uncontrolled hypertension
  ▪ uterine fibroids and endometriosis
  ▪ familial hyperlipidemias
  ▪ migraine headaches
  ▪ family history of estrogen-dependent cancer
  ▪ chronic thrombophlebitis
  ▪ diabetes mellitus (with vascular disease)
  ▪ gallbladder disease, hypertriglyceridemia, impaired liver function (consider transdermal estrogen)
  ▪ fibrocystic disease of the breasts

**WOMEN’S HEALTH INITIATIVE (WHI)** (launched in 1991)
• two non-randomized studies investigating health risks and benefits of HRT in healthy postmenopausal women 50-79 yr old
  ▪ continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg OD) in 16,608 women with an intact uterus
  ▪ estrogen-alone (CEE 0.625 mg) in 10,739 women with a previous hysterectomy
• both arms of the trial were stopped early because of evidence of increased risk of breast cancer, stroke, PE and CHD in the combined HRT arm, and increased risk of stroke with no CHD benefits in the estrogen-alone arm
• the apparent increase in CHD was in disagreement with results of previous observational trial
• results of the WHI study have since been challenged and revision of how CHD was diagnosed led to loss of statistical significance of the results
• benefits and risks reported as number of cases per 10,000 women each year

**Table 16. HRT Benefits versus Risks**

<table>
<thead>
<tr>
<th>Benefits</th>
<th>Risks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Vasomotor Symptoms:</strong> less frequent and severe with use of either combined or estrogen-alone HRT</td>
<td><strong>Stroke:</strong> 8 additional cases with combined HRT, and 12 additional cases for estrogen alone (WHI)</td>
</tr>
<tr>
<td><strong>Osteoporosis:</strong> 5 fewer cases of hip fractures and 47 fewer cases of all fractures with combined HRT. 6 fewer cases of hip fractures with estrogen alone</td>
<td><strong>DVT/PE:</strong> 18 additional cases with combined HRT, and 9 additional cases for estrogen-alone (WHI)</td>
</tr>
<tr>
<td><strong>Colon Cancer:</strong> 6 fewer cases with combined HRT (WHI). One additional case with estrogen-alone</td>
<td><strong>CHD:</strong> 7 additional MIs with combined HRT (WHI). Secondary analysis suggests greater absolute risk for women aged &gt;70 yr and for women who start HRT &gt;10 yr post-menopause</td>
</tr>
<tr>
<td><strong>Breast Cancer:</strong> 8 additional cases with combined HRT (WHI). Risk only increased after &gt;5 yr of combined HRT use. No increased risk for estrogen-alone</td>
<td><strong>Dementia and Mild Cognitive Impairment:</strong> 50% greater risk of developing dementia in women taking estrogen-alone after age 65. Risk is greater for women taking combined HRT. Risk of developing dementia was reduced for women taking HRT before age 65</td>
</tr>
</tbody>
</table>

**Urogynecology**

**Pelvic Relaxation/Prolapse**

**Etiology**
• relaxation, weakness, or defect in the cardinal and uterosacral ligaments which normally maintain the uterus in an anteflexed position and prevent it from descending through the urogenital diaphragm (i.e. levator ani muscles)
• related to:
  ▪ vaginal childbirth
  ▪ aging
  ▪ decreased estrogen (post-menopause)
  ▪ following pelvic surgery
  ▪ increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
  ▪ congenital (rarely)
  ▪ ethnicity (Caucasian women > Asian or African women)
  ▪ collagen disorders

**GENERAL CONSERVATIVE TREATMENT**
(for pelvic relaxation/prolapse and urinary incontinence)
• Kegel exercises
• local vaginal estrogen therapy
• vaginal pessary (intravaginal suspension disc)
### Table 17. Pelvic Prolapse

<table>
<thead>
<tr>
<th>Type</th>
<th>Clinical Features</th>
<th>Treatment</th>
</tr>
</thead>
</table>
| Uterine Prolapse (protrusion of cervix and uterus into vagina) | • Groin/back pain (stretching of uterosacral ligaments)  
  • Feeling of heaviness/pressure in the pelvis  
  • Worse with standing, lifting  
  • Worse at the end of the day  
  • Relieved by lying down  
  • Ulceration/bleeding (particularly if hypoestrogenic)  
  • ± urinary incontinence | • See General Conservative Treatment, GY34  
  • Vaginal hysterectomy ± surgical prevention of vault prolapse  
  • Consider additional surgical procedures if urinary incontinence, cystocele, rectocele, and/or enterocele are present |
| Vault Prolapse (protrusion of apex of vaginal vault into vagina, post-hysterectomy) | | • See General Conservative Treatment, GY34  
  • Sacralcolpopexy (vaginal vault suspension), sacrospinous fixation, or uterosacral ligament suspension |
| Cystocele (protrusion of bladder into the anterior vaginal wall) | • Frequency, urgency, nocturia  
  • Stress incontinence  
  • Incomplete bladder emptying ± associated increased incidence of urinary tract infections – may lead to renal impairment | • See General Conservative Treatment, GY34  
  • Anterior colporrhaphy (“anterior repair”)  
  • Consider additional/alternative surgical procedure if documented urinary stress incontinence |
| Rectocele (protrusion of rectum into posterior vaginal wall) | • Straining/digitation to evacuate stool  
  • Constipation | • See General Conservative Treatment, GY34  
  • Also laxatives and stool softeners  
  • Posterior colporrhaphy (“posterior repair”), plication of endopelvic fascia and perineal muscles approximated in midline to support rectum and perineum (can result in dyspareunia) |
| Enterocele (prolapse of small bowel in upper posterior vaginal wall) | | • Similar to hernia repair  
  • Contents reduced, neck of peritoneal sac ligated, uterosacral ligaments, and levator ani muscles approximated |

### Grading of Pelvic Organ Prolapse
- **0** = no descent during straining  
- **1** = distal portion of prolapse > 1 cm above level of hymen  
- **2** = distal portion of prolapse ≤ 1 cm above or below level of hymen  
- **3** = distal portion of prolapse > 1 cm below level of hymen but without complete vaginal eversion  
- **4** = complete eversion of total length of lower genital tract  

**Procidentia:** Failure of genital supports and complete protrusion of uterus through the vagina.

The only true hernia of the pelvis is an **ENTEROCELE** because peritoneum herniates with the small bowel.

---

**Figure 14. Pelvic anatomy**

**Figure 15. Rectocele, cystocele, uterine prolapse, enterocele**
Urinary Incontinence

- see Urology, U6

STRESS INCONTINENCE

Risk Factors for Stress Incontinence in Women
- pelvic prolapse
- pelvic surgery
- vaginal delivery
- hypoestrogenic state (post-menopause)
- age
- smoking
- neurological/pulmonary disease

Treatment
- see General Conservative Treatment, GY34
- surgical
  - tension-free vaginal tape (TVT), tension-free obturator tape (TOT), prosthetic/fascial slings or retropubic bladder suspension (Burch or Marshall-Marchetti-Krantz procedures)

URGE INCONTINENCE

Definition
- urine loss associated with an abrupt, sudden urge to void
- “overactive bladder”
- diagnosed based on symptoms

Etiology
- idiopathic (90%)
- detrusor muscle overactivity (“detrusor instability”)

Associated Symptoms
- frequency, urgency, nocturia, leakage

Treatment
- behaviour modification (reduce caffeine/liquid, smoking cessation, regular voiding schedule)
- Kegel exercises
- medications
  - anticholinergics: oxybutinin (Ditropan®), tolterodine (Detrol®), solifenacin (VESIcare®)
  - tricyclic antidepressants: imipramine

Gynecological Oncology

Uterus

ENDOMETRIAL CARCINOMA

Epidemiology
- most common gynecological malignancy in North America (40%); 4th most common cancer in women
- 2-3% of women develop endometrial carcinoma during lifetime
- mean age is 60 yr
- majority are diagnosed in early stage due to detection of symptoms
- 85-90% 5-yr survival for stage I disease
- 70-80% overall 5-yr survival for all stages

Risk Factors
- Type I: excess estrogen (estrogen unopposed by progesterone)
  - obesity
  - PCOS
  - unbalanced HRT (balanced HRT is protective)
  - nulliparity
  - late menopause
  - estrogen-producing ovarian tumours (e.g. granulosa cell tumours)
  - HNPCC (hereditary non-polyposis colorectal cancer)/Lynch II syndrome
  - tamoxifen

Incidence of Malignant Gynecological Lesions in North America
- endometrium > ovary > cervix > vulva > vagina > fallopian tube

Complications of Therapy:
- Surgical site infection
- Lymphedema
- Radiation fibrosis
- Cystitis
- Proctitis
• Type II: not estrogen-related
  • possibly tamoxifen

Classification and Clinical Features
• Type I (well-differentiated endometrioid adenocarcinoma) ~80% of cases:
  • postmenopausal bleeding in majority, abnormal uterine bleeding in majority of affected premenopausal women (menorrhagia, intermenstrual bleeding)
• Type II (serous, clear cell carcinoma, grade 3 endometrioid, undifferentiated, carcinosarcoma) ~15% of cases:
  • may not present with bleeding in early stage, more likely to present with advanced stage disease with symptoms like ovarian cancer (i.e. bloating, bowel dysfunction, pelvic pressure)

Investigations
• endometrial sampling:
  • office endometrial biopsy
  • D&C ± hysteroscopy
  • pelvic ultrasound (in women where adequate endometrial sampling not feasible without invasive methods)
  • not acceptable as alternative to pelvic exam or endometrial sampling to rule out cancer

Table 18. FIGO Staging of Endometrial Cancer (2009)

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>IIIB</td>
<td>Vaginal ± parametral involvement</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Note: endocervical glandular involvement is now considered as Stage I (previously Stage II)

Spread
• direct extension is most common
• lymphatic spread to pelvic and para-aortic nodes
• transtubal dissemination to peritoneal cavity
• hematogenous spread (usually to lungs, liver)

Treatment
• surgical: hysterectomy/bilateral salpingo-oophorectomy (BSO) and pelvic washings ± pelvic and para-aortic node dissection ± omentectomy
• goals: diagnosis, staging, treatment, defining optimal adjuvant treatment
• laparoscopic approach associated with improved quality of life (optimal for most patients)
• adjuvant radiotherapy (for improved local control in patients at risk for local recurrence) and adjuvant chemotherapy (in patients at risk for distant recurrence or with metastatic disease): based on presence of poor prognostic factors in definitive pathology
• chemotherapy: often used for recurrent disease (especially if high grade or aggressive histology)
• hormonal therapy: progestins can be used for recurrent disease (especially if low grade)

UTERINE SARCOMA
• rare; 2-6% of all uterine malignancies
• arise from stromal components (endometrial stroma, mesenchymal or myometrial tissues)
• behave more aggressively and are associated with worse prognosis than endometrial carcinoma; 5-yr survival is 35%
• vaginal bleeding is most common presenting symptom
### Table 19. Summary of Uterine Sarcoma Subtypes and Features

### Ovary

**BENIGN OVARIAN TUMOURS**

- see Table 21
- many are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
  - pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
  - peritoneal irritation may result from an infarcted tumour – rare
MALIGNANT OVARIAN TUMOURS

• see Table 21

Epidemiology
• lifetime risk 1.4% (1/70)
• in women >50 yr, more than 50% of ovarian tumours are malignant
• causes more deaths in North America than all other gynecologic malignancies combined
• 4th leading cause of cancer death in women
• 65% epithelial; 35% non-epithelial
• 5-10% of epithelial ovarian cancers are related to hereditary predisposition

Risk Factors (for epithelial ovarian cancers)
• excess estrogen:
  ▫ nulliparity
  ▫ early menarche/late menopause
• age
• family history of breast, colon, endometrial, ovarian cancer
• race: Caucasian

Protective Factors (for epithelial ovarian cancers)
• OCP: likely due to ovulation suppression (significant reduction in risk even after 1 yr of use)
• pregnancy/breastfeeding
• tubal ligation (recently questioned)
• hysterectomy (without removal of ovaries)
• BSO (prophylactic surgery performed for this reason in high risk women – i.e. BRCA mutation carriers)

Screening
• no effective method of mass screening
• routine CA-125 level measurements or U/S not recommended
  ▫ high false positive rates
• controversial in high risk groups: transvaginal U/S and CA-125, starting age 30 (no consensus on interval)
  ▫ familial ovarian cancer (>1 first degree relative affected, BRCA-1 mutation)
  ▫ other cancers (e.g. endometrial, breast, colon)
• BRCA-1 or BRCA-2 mutation: may recommend prophylactic bilateral oophorectomy after age 35 or when child-bearing is completed

Clinical Features
• most women with epithelial ovarian cancer present with advanced stage disease since often “asymptomatic” until disseminated disease (symptoms with early stage disease are vague and non-specific)
• when present, symptoms may include:
  ▫ abdominal symptoms (nausea, bloating, dyspepsia, anorexia, early satiety)
  ▫ symptoms of mass effect
    ▪ increased abdominal girth – from ascites or tumour itself
    ▪ urinary frequency
    ▪ constipation
  ▫ postmenopausal bleeding; irregular menses if pre-menopausal (rare)

Low Malignant Potential (also called “Borderline”) Tumours
• pregnancy, OCP and breastfeeding are protective factors
• ~15% of all epithelial ovarian tumours
• tumour cells display malignant characteristics histologically, but no invasion is identified
• able to metastasize, but not commonly
• treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
• NO proven benefit of chemotherapy
• generally slow growing, excellent prognosis
  ▫ 5-yr survival >99%
  ▫ recurrences tend to occur late, may be associated with low grade serous carcinoma

Effects of screening on ovarian cancer mortality: The prostate, lung, colorectal and ovarian cancer screening randomized controlled trial JAMA 2011;305:2295-2303

Objective: To evaluate the effect of screening for ovarian cancer with CA-125 and transvaginal ultrasound on mortality in the prostate, lung, colorectal and ovarian (PLCO) cancer screening trial.

Participants: 78,216 women aged 55-74 yr.

Study Groups: Intervention group – annual screening with CA-125 for 6 yr, transvaginal ultrasound for 4 yr; control group – no CA-125 or transvaginal ultrasound screening, received usual medical care.

Follow-up: Maximum 13 yr (median, 12.4 yr).

Outcome Measures: Mortality from ovarian cancer, including primary fallopian tube cancers. Secondary outcomes included ovarian cancer incidence and complications associated with screening, examinations and diagnostic procedures.

Results: Of those diagnosed with ovarian cancer in the intervention and usual care group, the mortality was 3.1% and 2.6% respectively. 15% of women undergoing diagnostic evaluation following a false positive screening test suffered a complication of the procedure.

Conclusions: Simultaneous screening with CA-125 and transvaginal ultrasound compared with usual care did not reduce ovarian cancer mortality. Diagnostic evaluation following a false positive screening test was associated with complications.

Investigation of Suspicious Ovarian Mass

- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynecologic oncologist
  - bimanual examination
  - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
  - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for pre-operative gynecologic oncology referral (see sidebar)
- bloodwork: CA-125 for baseline, CBC, liver function tests, electrolyte, creatinine
- radiology:
  - bone scan or PET scan not indicated
  - transvaginal ultrasound best to visualize ovaries
  - CT scan abdomen and pelvis to look for metastatic disease
- try to rule out other primary source if suspected, based on:
  - occult blood per rectum: endoscopy ± barium enema
  - gastric symptoms, gastroscopy ± upper GI series
  - abnormal vaginal bleeding, endometrial biopsy: rule out concurrent endometrial cancer, colposcopy ± ECC to rule out cervical cancer if abnormal cervix
  - breast lesion identified or risk factors present: mammogram

A Risk of Malignancy Incorporating CA125, Ultrasound and Menopausal Status for the Accurate Preoperative Diagnosis of Ovarian Cancer
BJOG 1990;97:922-929
RMI = U x M x CA-125

Ultrasound Findings (1 pt for each)
- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions
- 
  - U = 1 (for U/S scores of 0 or 1)
  - U = 4 (for U/S scores of 2-5)

Menopausal Status
- Postmenopausal: M = 4
- Pre-menopausal: M = 1

Absolute Value of CA-125 Serum Level
- For RMI > 200: Gynecologic oncology referral is recommended

FIGO: International Federation of Gynecology and Obstetrics

Cervix

BENIGN CERVICAL LESIONS
- Nabothian cyst/inclusion cyst
  - no treatment required
- endocervical polyps
  - treatment is polypectomy (office procedure)

MALIGNANT CERVICAL LESIONS

Epidemiology
- majority are squamous cell carcinomas (95%); adenocarcinomas increasing (5%); rare subtypes include small cell, adenosquamous
- 8,000 deaths annually in North America
- annual Pap test reduces a woman’s chance of dying from cervical cancer from 0.4% to 0.05%
- average age at presentation: 52 yr old

Etiology
- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from squamous to columnar)
  - a new squamocolumnar junction forms as a result
- the transformation zone (TZ) is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (HPV) to get dysplasia
- dysplasia → carcinoma in situ (CIS) → invasion
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

Risk Factors
- HPV infection
  - see Sexually Transmitted Infections, GY27
  - high risk of neoplasia associated with types 16, 18
  - low risk of neoplasia associated with types 6, 11
  - >99% of cervical cancers contain one of the high risk HPV types
- high risk behaviours (risk factors for HPV infection)
  - multiple partners
  - other STIs (HSV, trichomonas)
  - early age at first intercourse
  - high risk male partner
- smoking
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
  - immigrant Canadians
  - First Nations Canadians
  - geographically isolated Canadians
  - sex-trade workers
  - low socioeconomic status

Malignant Ovarian Tumour Prognosis
5-yr Survival
- Stage I 75-95%
- Stage II 60-75%
- Stage III 23-41%
- Stage IV 11%

Figure 16. The cervix

Causes of Elevated CA-125
- Age influences reliability of test as a tumour marker
- 50% sensitivity in early stage ovarian cancer (poor) — therefore not good for screening

Malignant
- Gyne: ovary, uterus
- Non-Gyne: pancreas, stomach, colon, rectum

Non Malignant
- Gyne: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gyne: cirrhosis, pancreatitis, renal failure
Cervical Cancer Screening Guidelines (Pap Test)
• see Family Medicine, FM4

Clinical Features
• squamous cell carcinoma (SCC): exophytic, fungating tumour
• adenocarcinoma: endophytic, with barrel-shaped cervix
• early
  • asymptomatic
  • discharge: initially watery, becoming brown or red
  • post-coital bleeding
• late
  • 80-90% present with bleeding: either post-coital, postmenopausal or irregular bleeding
  • pelvic or back pain (extension of tumour to pelvic walls)
  • bladder/bowel symptoms
• signs
  • friable, raised, reddened or ulcerated area visible on cervix

The Bethesda Classification System is based on cytological results of a Pap test that permits the examination of cells but not tissue structure. The diagnosis of cervical intraepithelial neoplasia (CIN) or cervical carcinoma requires a tissue sample, obtained by biopsy of suspicious lesions (done during colposcopy), to make a histologic diagnosis.

Figure 17. Decision making chart for Pap test (not applicable for adolescents)
Adapted from Ontario Cervical Screening Practice Guidelines. May 2012. Cervical screening guidelines unique to each province.
Diagnosis
- see Colposcopy, GY9
- apply acetic acid and identify acetowhite lesions, punctation, mosaicism, and abnormal blood vessels to guide cervical biopsy
- endocervical curettage (ECC) if entire lesion is not visible or no lesion visible
- diagnostic excision (loop electrosurgical excision procedure, LEEP) if:
  - lesion extends into endocervical canal
  - positive ECC
  - discrepancy between Pap test results and colposcopy
  - microinvasive carcinoma
- consider cold knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- tests permitted for FIGO clinical staging include: physical exam (including EUA), cervical biopsy (including cone biopsy), proctoscopy/cystoscopy, IVF, ultrasound liver/kidneys, CXR, LFTs
- MRI and/or CT and/or PET scan often done to facilitate planning of radiation therapy, results do not influence clinical stage

Treatment: Prevention and Management

Prevention: HPV Vaccine
- two vaccines currently approved (Gardasil®, Cervarix®)

| Table 25. Comparison of Two Vaccines against Human Papillomavirus (HPV) |
|-----------------|-----------------|
| Gardasil®  | Cervarix®  |
| Viral strains covered | 6, 11, 16, 18 | 16, 18 |
| Route of administration | IM | IM |
| Schedule of dosing | 0, 2, 6 mo | 0, 1, 6 mo |
| Side effects | Local: redness, pain, swelling | Local: redness, pain, swelling |
|               | General: headache, low grade fever, GI upset | General: headache, low grade fever, GI upset |
| Approved age | Females age 9-45, males age 9-26 | Females age 10-25 |
| Contraindications | Pregnant women and women who are nursing (limited data) |

- for optimal benefit of vaccination, should be administered before onset of sexual activity (i.e. before exposure to virus)
- may be given at the same time as Hep B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease
- conception should be avoided until 30 d after last dose of vaccination

During pregnancy:
- CIN II or III suspected or diagnosed during pregnancy, repeat colposcopy and treatment delayed until 8-12 wk after delivery

<table>
<thead>
<tr>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage IA2 (no LVSI)</td>
</tr>
<tr>
<td>• Trachelectomy (removal of only the cervix) if future fertility desired (and lesion ≤2 cm)</td>
</tr>
<tr>
<td>• Simple hysterectomy if future fertility is not desired</td>
</tr>
<tr>
<td>Stage IA2, IB1</td>
</tr>
<tr>
<td>• Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes under study)</td>
</tr>
<tr>
<td>• Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy</td>
</tr>
<tr>
<td>• Advantage is that ovaries can be spared if pre-menopausal</td>
</tr>
<tr>
<td>• For fertility preservation, may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease</td>
</tr>
<tr>
<td>• Concurrent chemoradiation therapy if adverse high risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria and/or positive margins</td>
</tr>
<tr>
<td>Stages IB2 (&gt;4 cm), II, III, IV</td>
</tr>
<tr>
<td>• Primary chemoradiation therapy</td>
</tr>
<tr>
<td>• PET/CT to grade: evaluate pelvic and para-aortic nodes</td>
</tr>
<tr>
<td>• For positive nodes on PET: primary chemoradiation with extended field RT</td>
</tr>
<tr>
<td>• Hysterectomy generally not suggested following primary treatment with curative intent</td>
</tr>
</tbody>
</table>

Abnormal Pap Tests in Pregnancy
- incidence: 1/2,200
- Pap test at all initial prenatal visits
  - if abnormal Pap or suspicious lesion, refer to colposcopy
  - if diagnostic conization required, should be deferred until second trimester (T2) to minimize risk of pregnancy loss
- if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
- if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
  - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility) or concurrent chemoradiation therapy
  - recommendations in T2/T3: delay of therapy until viable fetus and C/S for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

Vulva

BENIGN VULVAR LESIONS

Non-Neoplastic Disorders of Vulvar Epithelium
- biopsy is necessary to make diagnosis and/or rule out malignancy
- hyperplastic dystrophy (squamous cell hyperplasia)
  - surface thickened and hyperkeratotic
  - pruritus most common symptom
  - typically postmenopausal women
  - treatment: 1% fluorinated corticosteroid ointment bid for 6 wk
- lichen sclerosis
  - subepithelial fat becomes diminished, labia become thin and atrophic, membrane-like epithelium, labial fusion
  - pruritus, dyspareunia, burning
  - figure of 8’ distribution
  - most common in postmenopausal women but can occur at any age
  - treatment: ultrapotent topical steroid 0.05% clobetasol x 2-4 wk then taper down
• mixed dystrophy (lichen sclerosis with epithelial hyperplasia)
  ▪ hyperkeratotic areas with areas of thin, shiny epithelium
  ▪ treatment: fluorinated corticosteroid ointment

Tumours
• papillary hidradenoma, nevus, fibroma, hemangioma

MALIGNED VULVAR LESIONS

Epidemiology
• 5% of genital tract malignancies
• 90% squamous cell carcinoma; remainder melanomas, basal cell carcinoma, Paget’s disease, Bartholin’s gland carcinoma
  ▪ Type I disease: HPV-related (50-70%)
    • more likely in younger women
  ▪ 90% of vulvar intraepithelial neoplasia (VIN) contain HPV DNA (usually types 16, 18)
  ▪ Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
    • usually postmenopausal women

Risk Factors
• HPV infection (see above)
• VIN (vulvar intraepithelial neoplasia): precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
  ▪ progression to cancer rarely occurs with appropriate management
  ▪ treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)

Clinical Features
• many patients asymptomatic at diagnosis (many also deny or minimize symptoms)
• most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
• localized pruritus or lesion most common
• less common: raised red, white or pigmented plaque, ulcer, bleeding, discharge, pain, dysuria
• patterns of spread
  ▪ local
  ▪ groin lymph nodes (usually inguinal → pelvic nodes)
  ▪ hematogenous

Investigations
• ± colposcopy
• ALWAYS biopsy any suspicious lesion

<td>Individualized, Palliative therapy</td>
</tr>
<tr>
<td></td>
<td>Distant mets including pelvic LN</td>
<td>Individualized, Palliative therapy</td>
</tr>
</tbody>
</table>
Prognosis
- depends on stage – particularly nodal involvement (single most important predictor followed by tumour size)
- lesions >4 cm associated with poorer prognosis
- overall 5 yr survival rate: 79%

Vagina

BENIGN VAGINAL LESIONS
- inclusion cysts
  - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
  - no treatment required
- endometriosis
  - dark lesions that tend to bleed at time of menses
  - treatment: excision
- Gartner’s duct cysts
  - remnants of Wolffian duct, seen along side of cervix
  - treatment: conservative unless symptomatic
- urethral diverticulum
  - can lead to recurrent urethral infection, dyspareunia
  - treatment: surgical correction if symptomatic

MALIGNANT VAGINAL LESIONS

Epidemiology
- primary carcinomas of the vagina represent 2-3% of malignant neoplasms of the female genital tract
- 80-90% are squamous cell carcinoma
- more than 50% diagnosed between 70-90 yr old

Risk Factors
- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

Investigations
- cytology
  - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy!)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol’s iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are actually metastatic from one of these sites)
- staging (see Table 29)

Clinical Features

Table 28. Clinical Features of Malignant Vaginal Lesions

<table>
<thead>
<tr>
<th>Type</th>
<th>Clinical Features</th>

</thead>
<tbody>
<tr>
<td>Vaginal Intra-Epithelial Neoplasia (VAIN)</td>
<td>Grades: analogous to cervical dysplasia</td>
</tr>
</tbody>
</table>
| Squamous Cell Carcinoma (SCC) | Most common site is upper 1/3 of posterior wall of vagina
|                               | Asymptomatic                                                                     |
|                               | Painless discharge and bleeding                                                   |
|                               | Vaginal discharge (often foul-smelling)                                          |
|                               | Vaginal bleeding especially during/after coitus                                   |
|                               | Urinary or/and rectal symptom 2° to compression                                  |
| Adenocarcinoma                | Most are metastatic, usually from cervix, endometrium, ovary or colon
|                               | Most primaries are clear cell adenocarcinomas                                    |
|                               | 2 types: non-DES and DES syndrome                                                 |

Diethylstilbestrol (DES) Syndrome
- fetal exposure to DES (due to maternal use) predisposes to cervical or vaginal clear cell carcinoma: occurs in 30-95% of exposed females
- if exposed, <1 in 1,000 risk of developing clear cell adenocarcinoma
- clinical features
  - adenosis is persistent Müllerian type glandular epithelium in vagina
  - malformations of upper vagina, cervix, and interior of uterus (T-shaped); cockscomb or hooded cervix, cervical collar and pseudopolyps of cervix
- patients with DES exposure should have annual Pap tests (cervix and vagina) and digital vaginal exam for subepithelial masses
  - if any abnormality, refer for colposcopy
Table 29. FIGO Staging Classification of Vaginal Cancer (Clinical Staging) and Treatment

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
<th>Treatment</th>
</tr>
</thead>
</table>
| 0     | Intraepithelial neoplasia (VAIN), carcinoma in situ | • Must rule out invasive cancer via biopsies and colposcopy prior to conservative treatment  
• Laser ablation vs. surgical excision vs. local immunotherapy (e.g. imiquimod) |
| I     | Limited to the vaginal wall | • Radiation is mainstay of therapy: combination of brachytherapy and external beam radiation  
• In certain situations where surgery has a role in management:  
1. Stage I disease involving upper posterior vagina  
2. Young patients who require radiation therapy  
3. Stage IVA disease, particularly if rectovaginal or vesicovaginal fistula is present  
4. In patients with a central recurrence after radiation therapy  
• Limited reported evidence with chemoradiation |
| II    | Involves subvaginal tissue, NO pelvic wall extension | |
| III   | Pelvic wall extension | |
| IV    | Extension beyond true pelvis OR bladder/rectum involvement | |
| IVA   | Bladder + rectal mucosal spread = extension beyond true pelvis | 1. Stage I disease involving upper posterior vagina  
2. Young patients who require radiation therapy  
3. Stage IVA disease, particularly if rectovaginal or vesicovaginal fistula is present  
4. In patients with a central recurrence after radiation therapy |
| IVB   | Spread to distant organs | |

Fallopian Tube

- least common site for carcinoma of female reproductive system (0.3%)  
- usually serous epithelial carcinoma  
- recently considered to be origin of serous ovarian cancer  
- more common in fifth and sixth decade

Clinical Features

- classic triad present in minority of cases, but very specific  
  - watery discharge (most specific) = "hydrops tubae profluens"  
  - vaginal bleeding or discharge in 50% of patients  
  - crampy lower abdominal/pelvic pain  
- most patients present with a pelvic mass (see Ovarian Cancer, GY39 for guidelines regarding diagnosis/investigation)

Treatment

- as for malignant epithelial ovarian tumours

Gestational Trophoblastic Disease/Neoplasia (GTD/GTN)

- refers to a spectrum of proliferative abnormalities of the trophoblast

Epidemiology

- 1/1000 pregnancies  
- marked geographic variation – as high as 1/125 in Taiwan  
- 80% benign, 15% locally invasive, 5% metastatic  
- cure rate >95%

HYDATIDIFORM MOLE (Benign GTD)

Complete Mole

- most common type of hydatidiform mole  
- diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues or membranes present  
- 46XX or 46XY, chromosomes completely of paternal origin (90%)  
- 2 sperm fertilize empty egg or 1 sperm with reduplication  
- 15-20% risk of progression to malignant sequelae  
- risk factors  
  - geographic (South East Asia most common)  
  - others (maternal age >40 yr, β-carotene deficiency, vitamin A deficiency) – not proven  
- clinical features  
  - often present during apparent pregnancy with abnormal symptoms/findings:  
    - vaginal bleeding (97%)  
    - excessive uterine size for LMP (51%)  
    - theca-lutein cysts >6 cm (50%)  
    - preeclampsia (27%)  
    - hyperemesis gravidarum (26%)  
    - hyperthyroidism (7%)  
    - β-hCG >100,000 IU/L  
    - no fetal heart beat detected

Prognosis

5-yr Survival Rates

- Stage I: 70%  
- Stage II: 40%  
- Stage III: 30%  
- Stage IV: 15-20%

With development of hypertension early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease!
Partial (or Incomplete) Mole
- focal trophoblastic hyperplasia and hydropic villi are associated with fetus or fetal parts
- often triploid (XXX, XYY, XXX) with chromosome complement from both parents
  - usually related to single ovum fertilized by two sperm
- low risk of progression to malignant sequelae (<4%)
- associated with fetus, which may be growth-restricted and/or have multiple congenital malformations
- clinical features
  - typically present similar to threatened/spontaneous/missed abortion
  - pathological diagnosis often made after D&C

Investigations
- quantitative β-hCG levels (tumour marker) abnormally high for gestational age
  - U/S findings:
    - if complete: no fetus (classic “snow storm” due to swelling of villi)
    - if partial: molar degeneration of placenta ± fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
  - CXR (may show metastatic lesions)
  - features of molar pregnancies at high risk of developing persistent GTN post-evacuation
    - local uterine invasion as high as 31%
    - β-hCG >100,000 IU/L
    - excessive uterine size
    - prominent theca-lutein cysts

Treatment
- suction D&C with sharp curettage and oxytocin
  - Rhogam® if Rh negative
- consider hysterectomy (if patient no longer desires fertility)
- prophylactic chemotherapy of no proven benefit
- chemotherapy for GTN if develops after evacuation

Follow-up
- contraception required to avoid pregnancy during entire follow-up period
- serial β-hCGs (as tumour marker) every week until negative x 3 (usually takes several wk), then monthly for 6-12 mo prior to trying to conceive again
- increase or plateau of β-hCG indicates GTN → patient needs chemotherapy

GTN (MALIGNANT GTD)

Invasive Mole or Persistent GTN
- diagnosis made by rising or plateau in β-hCG, development of metastases following treatment of documented molar pregnancy (see sidebar)
- histology: molar tissue from D&C
- metastases are rare (4%)

Choriocarcinoma
- often present with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
- may follow molar pregnancy, abortion, ectopic, or normal pregnancy

Placental-site Trophoblastic Tumour
- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low β-hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

CLASSIFICATION of GTN
- non-metastatic
  - ~15% of patients after molar evacuation
  - may present with abnormal bleeding
  - all have rising or plateau of β-hCG
  - negative metastases on staging investigations
- metastatic
  - 4% patients after treatment of complete molar pregnancy
  - metastasis more common with choriocarcinoma which tends toward early vascular invasion and widespread dissemination
  - if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
    - lungs (80%): cough, hemoptysis, CXR lesion(s)
    - vagina (30%): vaginal bleeding, “blue lesions” on speculum exam
    - pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
    - liver (10%): elevated LFTs, U/S or CT findings
    - brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
highly vascular tumour → bleeding → anemia
• all have rising or plateau of β-hCG  
• classification of metastatic GTN  
  • divided into good prognosis and bad prognosis  
  • features of bad prognosis  
    – long duration (>4 mo from antecedent pregnancy)  
    – high pre-treatment β-hCG titre: >100,000 IU/24 h urine or >40,000 IU/L of blood  
    – brain or liver metastases  
    – prior chemotherapy  
    – metastatic disease following term pregnancy  
• good prognosis characterized by the absence of each of these features

Investigations – For Staging
• bloodwork: CBC, electrolytes, creatinine, β-hCG, TSH, LFTs  
• imaging: CXR, U/S pelvis, CT abdo/pelvis, CT brain  
• if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF β-hCG  
  • ratio of plasma β-hCG:CSF β-hCG <60 indicates metastases

Basics of Hematology

- over $10^{11}$ blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies
- lifespan of mature cells in blood:
  - erythrocytes (120 d), neutrophils (~1 d), platelets (10 d), lymphocytes (varies – memory cells persist for years)
- role of lymphoid organs
  - spleen: part of reticuloendothelial system, removes aged RBCs, removes antibody-coated bacteria/cells, site of antibody production
  - thymus: site of T-cell maturation, involutes with age
  - lymph nodes: sites of B and T-cell activation (adaptive immune response)

Figure 1. Hematopoiesis

- over $10^{11}$ blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies

*Normal values may vary depending on site and age

Approach to Interpreting a CBC
1. Consider values in the context of individual's baseline
   - up to 5% of population without disease may have values outside “normal” range
   - an individual may display a clinically significant change from their baseline without violating “normal” reference range
2. Is one cell line affected or are several?
   - if all lines are low: pancytopenia (see Pancytopenia, H7)
   - if RBCs and platelets are low: consider a microangiopathic hemolytic anemia (MAHA) (see H21)
   - if single cell line affected: see corresponding section in Common Presenting Problems, H5

Blood Film Interpretation

RED BLOOD CELLS

Size
- microcytic (MCV<80), normocytic (MCV=80-100), macrocytic (MCV>100)
- anisocytosis: RBCs with increased variability in size (increased RDW)
- iron deficiency anemia, hemolytic anemias, myelofibrosis, blood transfusion

Colour
- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
- iron deficiency anemia, anemia of chronic disease, sideroblastic anemia
- polychromasia: increased reticulocytes (pinkish-blue cells)
- increased RBC production by bone marrow

Shape
- poikilocytosis: increased proportion of RBCs of abnormal shape
- iron deficiency anemia, myelofibrosis

Table 2. Common Erythrocyte Shapes

<table>
<thead>
<tr>
<th>Shape</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discocyte</td>
<td>Biconcave disc</td>
<td>Normal RBC</td>
</tr>
<tr>
<td>Spherocyte</td>
<td>Spherical RBC (due to loss of membrane)</td>
<td>Hereditary spherocytosis, immune hemolytic anemia, post-transfusion</td>
</tr>
<tr>
<td>Elliptocyte/Ovalcyte</td>
<td>Oval-shaped, elongated RBCs</td>
<td>Hereditary elliptocytosis, megaloblastic anemia, megaloblastic anemia, myelofibrosis, iron-deficiency, MDS (myelodysplastic syndrome)</td>
</tr>
<tr>
<td>Schistocyte (helmet cell)</td>
<td>Fragmented cells (due to traumatic disruption of membrane)</td>
<td>Microangiopathic hemolytic anemia (HUS/ TTP DIC, preeclampsia, HELLP, malignant HTN), vasculitis, glomerulonephritis, prosthetic heart valve</td>
</tr>
<tr>
<td>Sickle cell</td>
<td>Sickle-shaped RBC (due to polymerization of hemoglobin S)</td>
<td>Sickle cell disorders: HbSC, HbSS</td>
</tr>
<tr>
<td>Codocyte (target cell)</td>
<td>“Bull’s eye” on dried film</td>
<td>Liver disease, hemoglobin SC, thalassemia, Fe deficiency, anemia</td>
</tr>
<tr>
<td>Dacrocyte (teardrop cell)</td>
<td>Single pointed end, looks like a teardrop</td>
<td>Myelofibrosis, thalassemia major, megaloblastic anemia</td>
</tr>
</tbody>
</table>

Clinical Use of RDW
- To distinguish the etiologies of microcytosis:
  - Iron deficiency: increased RDW (anisocytosis) as cells are of varying sizes in iron deficiency.
  - Thalassemia major: normal RDW (also expect a high RBC count) as cells are of similar size due to genetic defect in Hb.
Table 2. Common Erythrocyte Shapes (continued)

<table>
<thead>
<tr>
<th>Shape</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acanthocyte (spur cell)</td>
<td>Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipids)</td>
<td>Severe liver disease (spur cell anemia), starvation/anorexia, post-splenectomy</td>
</tr>
<tr>
<td>Echinocyte (burr cell)</td>
<td>RBC with numerous regularly spaced, small spiny projections</td>
<td>Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, storage artifact</td>
</tr>
<tr>
<td>Rouleaux formation</td>
<td>Aggregates of RBC resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins)</td>
<td>Pregnancy: most common cause; due to physiological increase in fibrinogen Inflammatory conditions: due to polyclonal immunoglobulins Plasma cell dyscrasias: due to monoclonal paraproteinaemia, e.g. multiple myeloma, macroglobulinaemia Storage artifact</td>
</tr>
</tbody>
</table>

HUS = Hemolytic uremic syndrome; TTP = Thrombotic thrombocytopenic purpura; DIC = disseminated intravascular coagulation; HELLP = hemolysis, elevated liver enzymes and low platelets

Table 3. RBC Inclusions (see Figure 2)

<table>
<thead>
<tr>
<th>Inclusions</th>
<th>Definition</th>
<th>Associated Conditions</th>

<tr>
<td>Heinz bodies</td>
<td>Denatured and precipitated hemoglobin</td>
<td>GPA deficiency (post-exposure to oxidant), thalassemia, unstable hemoglobins</td>
</tr>
<tr>
<td>Howell-Jolly</td>
<td>Small nuclear remnant resembling a pyknotic nucleus</td>
<td>Post-splenectomy, hyposplenism (sickle cell disease), neonates, megaloblastic anemia</td>
</tr>
<tr>
<td>Basophilic stippling</td>
<td>Deep blue granulations indicating ribosome aggregation</td>
<td>Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, hereditary (pyrimidine 5' nucleotidase deficiency)</td>
</tr>
<tr>
<td>Sideroblasts</td>
<td>Erythrocytes with Fe containing granules in the cytoplasm</td>
<td>Hereditary, idiopathic, drugs, hypothyroidism (see Sideroblastic Anemia, H15), myelodysplastic syndrome</td>
</tr>
</tbody>
</table>

BM = bone marrow; MPN = myeloproliferative neoplasm; MF = myelofibrosis

WHITE BLOOD CELLS
- lymphocytes: comprise 30–40% of WBCs; great variation in “normal” lymphocyte morphology
  - Reed-Sternberg cell: giant, multinucleated B-lymphocyte, only seen with bone marrow specimens
    - associations: primarily Hodgkin lymphoma, also seen in some non-Hodgkin lymphoma, CLL and EBV infection
  - smudge cells: lymphocytes damaged during blood film preparation indicating cell fragility
    - associations: chronic lymphocytic leukemia (CLL) and other lymphoproliferative disorders – pathognomonic in EBV infection
- neutrophils
  - normally only mature neutrophils (with 3-4 lobed nucleus) and band neutrophils (immediate precursor with horseshoe-shaped nucleus) are found in circulation
  - hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B12 or folate deficiency)
  - left shift (increased granulocyte precursors)
    - seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, myeloproliferative neoplasms (CML, MF)
- blasts
  - immature, undifferentiated precursors; associated with acute leukemia, MDS, G-CSF (growth factor that stimulates neutrophil production) use
  - Auer rods: clumps of granular material that form long needles in the cytoplasm of myeloblasts
    - pathognomonic for acute myeloid leukemia (AML)

PLATELETS
- small, purple, anuclear cell fragments

Bone Marrow Aspiration and Biopsy
- sites: posterior iliac crest, sternum
- possible analyses
  - aspiration: takes a fluid marrow sample for cellular morphology, flow cytometry, cytogenticities, molecular studies, microbiology (C&S, AFB, PCR)
  - biopsy: takes a sample of intact bone marrow to assess histology and immunohistochemistry

Indications
- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, solid tumours
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores (gold standard, but rarely done)
evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher’s disease)
evaluate fever of undetermined origin, suspected mycobacterial, fungal or parasitic infections,
or granulomatous disease
unexplained splenomegaly
confirm normal bone marrow in potential allogenic hematopoietic cell donor

Contraindications
• absolute: untreated hemophilia, severe DIC, infection over skin site
• relative: platelet count <10, recent warfarin use with INR >2.0, liver disease with associated
coaagulopathy
• thrombocytopenia is not a contraindication; may need platelet transfusion prior to procedure

Common Presenting Problems

Anemia
Definition
• a decrease in red blood cell (RBC) mass that can be detected by hemoglobin (Hb) concentration, hematocrit (Hct), and RBC count
  • adult males: Hb <130 g/L or Hct <0.41
  • adult females: Hb <120 g/L or Hct <0.36

Clinical Features
• history
  • symptoms of anemia: fatigue, malaise, weakness, dyspnea, decreased exercise tolerance, palpitations, headache, dizziness, tinnitus, syncope
  • acute vs. chronic, bleeding, systemic illness, diet, alcohol, family history
  • menstrual history: menorrhagia, menometrorrhagia, dysfunctional uterine bleeding
  • rule out pancytopenia (recurrent infection, mucosal bleeding/easy bruising)
• physical signs
  • HEENT: pallor in mucous membranes, palmar creases and conjunctiva at Hb <90 g/L (<9 g/dL), ocular bruits at Hb <55 g/dL (<5.5 g/dL), angular cheilosis, jaundice
  • cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
  • dermatologic: pallor in palmar skin creases at Hb <75 g/L, jaundice (if due to hemolysis), nail changes, glossitis

Investigations
• rule out dilutional anemia (low Hb due to increased effective circulating volume)
• CBC with differential (MCV, RDW, RBC count)
• reticulocyte count
• blood film
• rule out nutritional deficit, gastrointestinal and genitourinary disease in iron deficiency anemia
• additional laboratory investigations as indicated (see Microcytic Anemia, H12, Normocytic Anemia, H17 and Macrocytic Anemia, H22)
**Erythrocytosis**

**Definition**
- an increase in the number of RBCs: Hb >185 g/L or Hct >52% (males); Hb >165 or Hct >47% (females and African males)

**Etiology**
- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, "stress" (Gaisböck’s syndrome)
- absolute erythrocytosis

<table>
<thead>
<tr>
<th>Table 4. Etiology of Erythrocytosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
</tr>
<tr>
<td>------------------------------------</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

**Clinical Features**
- secondary to high red cell mass and hyperviscosity
  - headache, dizziness, tinnitus, visual disturbances, hypertensive symptoms
  - symptoms of angina, congestive heart failure, aquagenic pruritis
  - thrombosis (venous or arterial) or bleeding (abnormal platelet function)
  - physical findings
    - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

**Investigations**
- serum erythropoietin (EPO): increased EPO suggests autonomous production or hypoxia, and is used to rule out PV
  - search for tumour as source of EPO as indicated (e.g. abdominal U/S, CT head)
  - JAK-2 mutation analysis: positive in >96% of cases of PV
    - only send if low/normal EPO level
  - ferritin (iron deficiency can mask the diagnosis)

**Treatment**
- if primary: see PV, H39
- if secondary: treat underlying cause
  - O$_2$ for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours
  - often cardiologists will not treat high HCT in cyanotic patients (or will have high threshold)

---

**Thrombocytopenia**

**Definition**
- platelet count <150 x10$^9$/L

**Clinical Features**
- history: bleeding gums, epistaxis, bleeding post-surgical procedures, metromenorrhagia
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura
  - hemarthrosis and deep muscle hematomas are rarely initial signs in patients with primary hemostatic disorders
- see Disorders of Primary Hemostasis, H25, for complications

**Investigations**
- CBC and differential
- blood film
  - decreased production: other cell line abnormalities, blasts, hypersegmented PMNs, leukoerythroblastic changes
  - increased destruction: large platelets, schistocytes (seen in MAHA)
  - rule out platelet clumping
- work-up for nutritional deficiencies: B$_{12}$, RBC folate
- PT/INR, aPTT and fibrinogen if DIC suspected
- LFTs

**Must rule out factitious thrombocytopenia**: platelet clumping (secondary to EDTA antibodies from collection tube). This can be seen on blood film and confirmed by repeating in a citrated sample (i.e. using a sodium citrate tube to collect blood, rather than EDTA).
**Thrombocytopenia**

**Definition**
- platelet count >400 x10^9/L
- primary thrombocytopenia: due to myeloproliferative neoplasms [e.g. CML, polycythemia vera (PV), primary myelofibrosis, essential thrombocytosis (ET). Rarely associated with MDS]
- reactive/secondary thrombocytopenia: acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasms, ischemic injury); much more common than primary

**Clinical Features**
- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly can be seen in myeloproliferative neoplasms (MPNs)

**Investigations**
- CBC, peripheral blood film, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- if reactive process has been ruled out, bone marrow biopsy may be required to rule out MPN/MDS

**Treatment**
- primary: ASA ± cytoreductive agents
- secondary: treat underlying cause

**Pancytopenia**

**Definition**
- a decrease in all hematopoietic cell lines

**Clinical Features**
- anemia: fatigue
- leukopenia: recurrent infections
- thrombocytopenia: mucosal bleeding and ecchymoses

**Investigations**
- CBC and differential, blood film
- reticulocyte count
- investigate secondary causes as per history: HIV test, serum B12, RBC folate, ANA
- on history, inquire about drug (including OTC/herbal) and environmental exposures
- often requires bone marrow biopsy to determine cause
Neutrophilia

**Definition**
- different guidelines, but absolute neutrophil count (ANC) >7.7 x 10⁹/L

**Etiology**
- primary neutrophilia
  - chronic myeloid leukemia (CML)
    - other myeloproliferative disorders: PV, essential thrombocytosis (ET), myelofibrosis
    - hereditary neutrophilia (autosomal dominant)
  - chronic idiopathic neutrophilia in otherwise healthy patients
- secondary neutrophilia
  - smoking: most common cause of mild neutrophilia
  - infection: leukocytosis with left shift ± toxic granulation, Döhle bodies (intra-cytoplasmic structures composed of agglutinated ribosomes)
  - inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, burns
  - malignancy: hematologic (i.e. marrow invasion by tumour) and non-hematologic (especially large cell lung cancer)
  - stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
  - medications: glucocorticoids, β-agonists (e.g. epinephrine), lithium

**Clinical Features**
- look for signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
  - including lymph nodes and organomegaly
- examine oral cavity, teeth, peri-rectal area, genitals and skin for signs of infection

**Investigations**
- CBC and differential: mature neutrophils or bands >20% of total WBC suggests infection/inflammation
- blood film: Döhle bodies, toxic granulation, cytoplasmic vacuoles in infection
- review other blood counts
- may require bone marrow biopsy if MPN suspected

**Treatment**
- directed at underlying cause

Neutropenia

**Definition**
- mild: ANC 1.0-1.5 x 10⁹/L
- moderate: ANC 0.5-1.0 x 10⁹/L (risk of infection starts to increase)
- severe: ANC <0.5 x 10⁹/L
- profound: ANC <0.1 x 10⁹/L for >7 d

**Absolute Neutrophil Count (ANC) =**
WBC count x (%PMNs + %bands)

**Beware of fever + ANC <0.5 x10⁹/L = FEBRILE NEUTROPENIA**
Etiology

Clinical Features
- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. S. aureus, gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth and throat following colonization by opportunistic organisms
- avoid digital rectal exam

Investigations
- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs to bone marrow aspiration and biopsy

Treatment
- regular dental care: chronic gingivitis and recurrent stomatitis major sources of morbidity
- febrile neutropenia (see Infectious Diseases, ID39)
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
  - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, methotrexate)

**Lymphocytosis**

Definition
- absolute lymphocyte count >4 x 10^9/L

Etiology
- infection
  - viral infections (majority); particularly mononucleosis
  - TB, pertussis, brucellosis, toxoplasmosis
  - physiologic response to stress (e.g. trauma, status epilepticus)
  - hypersensitivity (e.g. drugs, serum sickness)
  - autoimmune (e.g. rheumatoid arthritis)
  - neoplasm (e.g. ALL, CLL, lymphoma)

Investigations
- peripheral smear

Treatment
- treat underlying cause

**Lymphopenia**

Definition
- absolute lymphocyte count <1.5 x 10^9/L

Etiology
- idiopathic CD4+ lymphocytopenia
- radiation
- HIV/AIDS, hepatitis B, hepatitis C
- malignancy/chemotherapeutic agents
- malnutrition, alcoholism
- autoimmune disease (e.g. SLE)

### Prophylactic Hematopoietic Colony-Stimulating Factors on Mortality and Infection

**Ann Intern Med 2007;147:400-411**

**Purpose:** To review the effects of colony-stimulating factor (CSF) on mortality, infections, and febrile neutropenia in patients undergoing chemotherapy or stem-cell transplant (SCT).

**Study Selection:** 148 RCTs comparing the effects of CSFs to either placebo or no therapy were included. Prophylactic CSFs were given concurrently with or after initiation of chemotherapy.

**Results:** There were no differences in all-cause mortality or infection-related death between CSF and placebo groups. Compared to placebo or no therapy, CSFs reduced infection rate (median rate 38.8% vs. 43.1%; rate ratio 0.85), microbiologically documented infections (MR 23.5% vs. 28.6%; rate ratio 0.86), and febrile neutropenia (MR 25.3% vs. 44.2%; rate ratio 0.71).

**Conclusions:** Prophylactic CSFs decrease infection rates and episodes of febrile neutropenia in patients undergoing chemotherapy or SCT, but have no effect on mortality.

**G-CSF = Neupogen® = Filgrastim**

Presence of smudge cells suggests a lymphoproliferative disorder if persistently elevated above 5.0 x10^9/L for >3 mo. Consider flow cytometry.

Presence of atypical lymphocytes suggests viral infection.
Clinical Features
• opportunistic infections (see Infectious Diseases, ID39)

Treatment
• treat underlying cause
• treat opportunistic infections aggressively and consider antimicrobial prophylaxis (see Infectious Diseases, ID47)

Eosinophilia

Definition
• absolute eosinophil count >0.5 x 10⁹/L

Etiology
• primary: due to clonal bone marrow disorder
  ▪ if no primary etiology identified, classified as hypereosinophilic syndrome
  ▪ 6 mo of eosinophilia with no other detectable causes
  ▪ can involve heart, bone marrow, CNS
• secondary:
  ▪ most common causes are parasitic (usually helminth) infections and allergic reactions
  ▪ less common causes:
  ▪ polyarteritis nodosa, see Rheumatology, RH19
  ▪ respiratory causes (asthma, eosinophilic pneumonia, Churg-Strauss)
  ▪ cholesterol emboli
  ▪ hematologic malignancy: CML, Hodgkin lymphoma, see H38, H43
  ▪ adrenal insufficiency, see Endocrinology, E35
  ▪ medications (penicillins)

Treatment
• treat underlying cause

Agranulocytosis

Definition
• severe depletion of granulocytes (neutrophils, eosinophils, basophils) from the blood and granulocyte precursors from bone marrow

Etiology
• associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine and ticlopidine
  ▪ immune-mediated destruction of circulating granulocytes by drug-induced antibodies or direct toxic effects upon marrow granulocytic precursors

Clinical Features
• abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

Prognosis
• high fatality without vigorous treatment

Investigations/Treatment
• discontinue offending drug
• pan-culture and screen for infection if patient is febrile (blood cultures x2, urine culture and chest x-ray as minimum, initiate broad-spectrum antibiotics)
• consider bone marrow aspirate and biopsy if cause unclear
• consider G-CSF

Leukemoid Reactions

• blood findings resembling those seen in certain types of leukemia which reflect the response of healthy BM to cytokines released due to infection or trauma
• leukocytosis >50 x 10⁹/L, marked left shift (myelocytes, metamyelocytes, bands in peripheral blood smear)

Etiology
• important to rule out CML
• differential diagnosis:
  ▪ myeloid progenitors: pneumonia, other acute bacterial infections, intoxications, burns, malignant disease, severe hemorrhage or hemolysis
  ▪ lymphoid progenitors: pertussis, TB, infectious mononucleosis
• monocytic progenitors: TB
Approach to Lymphadenopathy

History
- constitutional/B-symptoms: seen in TB, lymphoma, other malignancies
- exposures: cats (cat scratch – Bartonella henselae), ticks (Lyme disease – Borrelia burgdorferi), high risk behaviors (HIV)
- joint pain/swelling, rashes (connective tissue disorder)
- pruritus (seen in Hodgkin lymphoma)
- medications (can cause serum sickness → lymphadenopathy)

Physical Exam
- basic assessment: occipital, preauricular, submandibular, cervical, supra/infra-clavicular, axillary, epitrochlear, inguinal, popliteal nodes
  - characteristics of lymph nodes (see Table 6)
  - look for signs of infection in regions which lymph nodes drain
- determine if lymphadenopathy is localized or generalized
  - localized: typically reactive or neoplastic
    - cervical (bacterial/mycobacterial infections, ENT malignancies, metastatic cancer)
    - supraclavicular
      - right (mediastinal, bronchogenic, esophageal cancer)
      - left (gastric, gall bladder, pancreas, renal, testicular/ovarian cancer)
    - axillary (cat scratch fever, breast cancer, metastatic cancer)
    - epitrochlear (infections, sarcoidosis, lymphoma)
    - lower/inguinal (STDs, skin, cervix, vulva/penis, rectum/anus cancer)
- generalized: see Table 7
  - thorough examination required to assess for systemic disease

Investigations
- CBC and differential, blood film
- ± tuberculin test, HIV RNA, RPR/VDRL, monospot/EBV serology, ANA, imaging as indicated
- if localized and no symptoms suggestive of malignancy, can observe 3-4 wk (if no resolution → biopsy)
- excisional biopsy is preferred as it preserves node architecture (essential for diagnosing lymphoma)
- in difficult to access areas (retroperitoneal, mediastinal/hilar) multiple core biopsies may be more practical/feasible
- FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (use excisional biopsy instead)
  - helpful for recurrence of solid tumour malignancy

Table 6. Inflammatory vs. Neoplastic Lymph Nodes

<table>
<thead>
<tr>

The underlined conditions cause massive splenomegaly (spleen crosses midline or reaches pelvis).

**History**
- constitutional symptoms, feeling of fullness in LUQ
- signs or symptoms of infection or malignancy
- history of liver disease, hemolytic anemia or high-risk exposures

**Physical Exam**
- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell’s sign, Traube’s space, Nixon’s method) and palpation
- associated lymphadenopathy or hepatomegaly
- signs of CHF

**Investigations**
- CBC and differential, blood film
- as indicated: liver enzymes/liver function tests, reticulocyte count, Monospot®, haptoglobin, LDH, infectious and autoimmune workups
- imaging
  - ultrasound of abdomen/liver to rule out cirrhosis and portal vein thrombosis
  - echo for cardiac function
  - CT to rule out lymphoma

**Microcytic Anemia**
- MCV <80 fL
- see Figure 3, Approach to Anemia, H5

TIBC = total iron-binding capacity

**Iron Metabolism**

- average North American adult diet = 10-20 mg iron (Fe) daily
- absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid, ascorbic acid (vitamin C) and reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males have positive Fe balance; up to 20% of menstruating females have negative Fe balance

**Causes of Splenomegaly**
- CHINA
  - Cirrhosis/Congestion (portal HTN)
  - Hematological
  - Infectious
  - Neoplasm (malignant, non-malignant)
  - Autoimmune

**Does this Adult Patient have Splenomegaly?**
From The Rational Clinical Examination JAMA 2009; http://www.jamaevidence.com/content/3487298

**Study:** Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for detecting splenomegaly.

**Results:** On percussion, Nixon sign had a positive likelihood ratio (+LR) of 3.6 (95% CI, 1.8-7.3) and a negative likelihood ratio (-LR) of 0.41 (95% CI, 0.26-0.64). Percussion of Traube’s space had a +LR of 2.3 (95% CI, 1.8-2.9) and -LR of 0.48 (95% CI, 0.39-0.60), while Castell sign had a +LR of 1.2 (95% CI, 0.86-1.6) and -LR of 0.45 (95% CI, 0.38-1.1). On palpation, supine 1-handed palpation had a +LR of 1.2 (95% CI, 0.8-1.5) and -LR of 0.45 (95% CI, 0.30-1.0). Middleton hooking maneuver had a +LR of 1.3 (95% CI, 1.3-2.6) and -LR of 0.60 (95% CI, 0.49-0.83).

**Conclusions:** Palpation may have greater accuracy than percussion, but may be best when both are used in tandem. Specifically, Nixon sign and supine 1-handed palpation are the most accurate, respectively.
Iron Indices (see Table 9 and Figure 6)
- bone marrow aspirate: gold standard test for iron stores (rarely done)
- serum ferritin: most important blood test for iron stores
  - decreased in iron deficiency anemia
  - elevated in:
    - infection, inflammation, malignancy
    - liver disease, hyperthyroidism and iron overload
- serum iron: measure of all non-heme iron present in blood
  - varies significantly daily
  - virtually all serum iron is bound to transferrin, only a trace is free or complexed in ferritin
- total iron binding capacity (TIBC): total amount of transferrin present in blood
  - normally, one third of TIBC is saturated with iron
  - high specificity for decreased iron, low sensitivity
- saturation:
  - serum Fe divided by TIBC, expressed as a proportion or a percentage
  - low in iron deficiency anemia
- soluble transferrin receptor (sTfR):
  - reflects the availability of iron at the tissue level
  - the transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some is cleaved off and is present in circulation as sTfR
  - in iron deficient states more transferrin receptor is expressed on erythroblasts leading to an increase in sTfR
  - low in reduced erythropoiesis and iron overload
  - useful in determining iron deficiency in the setting of chronic inflammatory disorders (see Iron Deficiency Anemia, H14)

Iron Absorption and Transport (see Figure 6)
- dietary iron is absorbed in the duodenum (impaired by IBD, celiac disease, etc.)
- in circulation the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages and hepatocytes) to RBC precursors in the bone marrow

Iron Storage
- ferritin
  - ferric iron (Fe³⁺) complexed to a protein called apoferritin (hepatocytes are main ferritin storage site)
  - small quantities are present in plasma in equilibrium with intracellular ferritin
  - also an acute phase reactant – can be spuriously elevated despite low Fe stores in response to a stressor
- hemosiderin
  - aggregates or crystals of ferritin with the apoferritin partially removed
  - macrophage-monocyte system is main source of hemosiderin storage

Figure 6. Iron metabolism
Iron Deficiency Anemia

- see Pediatrics, P47
- most common cause of anemia in North America

**Etiology**
- increased demand
  - increased physiological need for iron in the body (e.g. pregnancy)
- decreased supply: dietary deficiencies (rarely the only etiology)
  - cow’s milk (infant diet)
  - “tea and toast” diet (elderly)
  - absorption imbalances
  - post-gastrectomy
  - malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis)
- increased losses
  - hemorrhage
    - obvious causes: menorrhagia, abnormal uterine bleeding, frank GI bleed
    - occult: peptic ulcer disease, GI cancer
  - hemolysis
    - intravascular (e.g. paroxysmal nocturnal hemoglobinuria (PNH), cardiac valve RBC fragmentation)
    - extravascular (e.g. immune hemolytic anemias)

**Clinical Features**
- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see Approach to Anemia, H5
- brittle hair, nail changes (brittle, koilonychia)
- Plummer-Vinson syndrome: dysphagia (esophageal webs), glossitis, angular stomatitis (inflammation and fissuring at the corners of the mouth)
- pica (appetite for non-food substances e.g. ice, paint, dirt)

**Investigations**
- iron indices, including soluble transferrin receptor (Figure 7)
  - low ferritin (<45 µg/L) is diagnostic of iron deficiency (Table 10)
  - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup (Figure 7)
- peripheral blood film
  - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
  - pencil forms, anisocytosis
  - target cells (thin)
- bone marrow (gold standard but rarely done)
  - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
  - intermediate and late erythroblasts show micronormoblastic maturation

**Table 10. The Utility of Ferritin in the Diagnosis of Iron Deficiency Anemia**

<tr>
<td>≤18</td>
<td>41.47</td>
</tr>
</tbody>
</table>

**Treatment**
- treat underlying cause
- supplementation
  - oral (tablets, syrup)
    - ferrous sulphate 325 mg tid, ferrous gluconate 300 mg tid, or ferrous fumarate 300 mg tid
    - supplement until anemia corrects, then continue for 3+ mo until serum ferritin returns to normal
    - oral iron should be taken with citrus juice to enhance absorption
  - IV (iron sucrose or dextran) can be used if patient cannot tolerate or absorb oral iron
• monitoring response
  • reticulocyte count will begin to increase after one wk
  • Hb normalizes by 10 g/L per wk (if no blood loss)
  • iron supplementation required for 4-6 mo to replenish stores

### Anemia of Chronic Disease

- see Pediatrics, P48

#### Etiology
- infection, malignancy, inflammatory and rheumatologic disease, chronic renal and liver disease, endocrine disorders (e.g. diabetes mellitus, hypothyroidism, hypogonadism, hypopituitarism)

#### Pathophysiology
- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
  - enterocyte trapping of iron → increased hepcidin inhibits ferroportin (→ iron into circulation)
  - macrophage trapping of iron → reduced plasma iron levels making iron relatively unavailable for new hemoglobin synthesis
  - marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present
- RBC survival is modestly decreased

#### Investigations
- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen)
- "classic" serum iron indices (see Table 9)
  - serum iron and TIBC low, % saturation normal
  - serum ferritin is normal or increased
- anemia of chronic disease often co-exists with iron deficiency (see sidebar)
- peripheral blood
  - mild: usually normocytic and normochromic
  - moderate: may be microcytic and normochromic
  - severe: may be microcytic and hypochromic
  - absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- bone marrow
  - normal or increased iron stores
  - decreased or absent staining for iron in erythroid precursors

#### Treatment
- treat underlying disease
- only treat anemia in patients who can benefit from a higher hemoglobin
- IV iron if no benefit from PO iron
- erythropoietin indicated in chronic renal failure. Not to be used if patient has concommitant curative solid tumour malignancy. Ensure Hb target <110 g/L

### Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic disease

#### Sideroblasts
- erythrocytes with iron-containing (basophilic) granules in the cytoplasm
- "normal": granules are small, randomly spread in the cytoplasm
  - found in healthy individuals
- "ring": iron deposits in mitochondria, forming a ring around the nucleus
  - abnormal, large granules
  - the hallmark of sideroblastic anemia

#### Etiology
- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare): X-linked; median survival 10 yr
- idiopathic (acquired)
  - aka refractory anemia with ringed sideroblasts: a subtype of MDS (see Myelodysplastic Syndromes, H36)
  - may be a preleukemic phenomenon (10% transform to AML)
- reversible
  - drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, hypothyroidism
Clinical Features
- anemia symptoms (see Approach to Anemia, H5)
- hepatosplenomegaly, Fe²⁺ overload syndrome

Investigations
- serum iron indices
  ▪ increased serum Fe²⁺, normal TIBC, increased ferritin, increased sTR
- blood film/bone marrow biopsy
  ▪ ringed sideroblasts (diagnostic hallmark)
  ▪ RBCs are hypochromic; can be micro-, normo-, or macrocytic
  ▪ anisocytosis, poikilocytosis, basophilic stippling

Treatment
- depends on etiology
  ▪ X-linked: high dose pyridoxine (vitamin B₆) in some cases
  ▪ acquired: EPO and G-CSF
  ▪ reversible: remove precipitating cause
- supportive transfusions for severe anemia

Lead Poisoning

Definition/Etiology
- blood lead levels greater than 80 µg/dL, possible symptomatology at 50 µg/dL.

Clinical Features
- identify source: consider occupational history, exposures history
- abdominal pain, constipation, irritability, difficulty concentrating

Treatment
- chelation therapy: dimercaprol and EDTA are first line agents

Thalassemia
- see Hemolytic Anemia – Thalassemia, H18

Normocytic Anemia
- MCV 80-100 fl.
- see Figure 3, Approach to Anemia, H5

Aplastic Anemia

Definition
- destruction of hematopoietic cells of the bone marrow leading to pancytopenia and hypocellular bone marrow

Epidemiology
- occurs at any age
- slightly more common in males

Etiology

<table>
<thead>
<tr>
<th>Table 11. Etiology of Aplastic Anemia</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Congenital</strong></td>
</tr>
<tr>
<td>Fanconi’s anemia</td>
</tr>
<tr>

</tr>
<tr>
<td>Toxins</td>
</tr>
<tr>
<td>Benzene/organic solvents</td>
</tr>
<tr>
<td>DDT, insecticides</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Clinical Features
- can present acutely or insidiously
- symptoms of anemia (see Approach to Anemia, H5), thrombocytopenia (see Thrombocytopenia, H6) and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)
Investigations
- exclude other causes of pancytopenia (Figure 3)
- CBC
  - anemia or neutropenia or thrombocytopenia (any combination) ± pancytopenia
  - decreased reticulocytes (<1% of the total RBC count)
- blood film
  - decreased number of normal RBCs
- bone marrow
  - aplasia or hypoplasia of marrow cells with fat replacement
  - decreased cellularity

Treatment
- remove offending agents
- supportive care (red cell and platelet transfusions, antibiotics)
  - judicious use so as to not increase the risk of immune sensitization to blood products
- immunosuppression
  - anti-thymocyte globulin: 50-60% of patients respond
  - cyclosporine
- allogenic bone marrow transplant

Hemolytic Anemia (HA)

Classification
- hereditary
  - abnormal membrane (spherocytosis, elliptocytosis)
  - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
  - abnormal hemoglobin synthesis (thalassemias, hemoglobinopathies)
- acquired
  - immune
    - hemolytic transfusion reaction, autoimmune HA (AIHA), drugs (e.g. penicillin), cold agglutinins
    - alloimmune (transfusion reaction, hemolytic disease of the fetus/newborn)
  - non-immune
    - microangiopathic HA (MAHA): thrombus in blood vessel causes RBCs to be sheared – associated with DIC, HUS/TTP, preeclampsia/HELLP, vasculitides, malignant hypertension
    - other causes: paroxysmal nocturnal hemoglobinuria (PNH), hypersplenism, march hemoglobinuria (exertional hemolysis), infection (e.g. malaria), snake venoms, mechanical heart valves
  - also classified as intravascular or extravascular:
    - intravascular: G6PD deficiency, TTP, DIC and PNH
    - extravascular: AIHA and hereditary spherocytosis

Clinical Features Specific to HA
- jaundice
- dark urine (hemoglobinuria, bilirubin)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

Investigations

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Thalassemia

Definition
- defects in production of the α or β chains of hemoglobin
  - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
- clinical manifestations and treatment depends on specific gene and number of alleles affected
- common features:
  - increasing severity with increasing number of alleles involved
  - hypochromic microcytic anemia
  - basophilic stippling, abnormally shaped RBCs on blood film

Pathophysiology
- defect may be in any of the Hb genes
  - normally 4α genes in total; 2 on each copy of chromosome 16
  - normally 2β genes in total; 1 on each copy of chromosome 11
  - fetal hemoglobin, HbF (αβγδ), switches to adult forms HbA (αβ2) and HbA2 (αδ2) at 3-6 mo of life
  - HbA constitutes 97% of adult hemoglobin
  - HbA2 constitutes 3% of adult hemoglobin

β-Thalassemia Minor (Thalassemia Trait)

Definition
- defect in single allele of β gene (heterozygous)
- common in people of Mediterranean and Asian descent

Clinical Features
- None; a palpable spleen is very rare

Investigations
- Hb 100-140 g/L or 9-14 g/dL, MCV<70, normal Fe, normal RBC count
- peripheral blood film – microcytosis basophilic stippling
- Hb electrophoresis
  - specific: HbA2 increased to 2.5-5% (normal 1.5-3.5%)
  - non-specific: 50% have slight increase in HbF

Treatment
- no treatment required
- genetic counselling for patient and family

β-Thalassemia Major

Definition
- defect in both alleles of β gene (homozygous, autosomal recessive)

Pathophysiology
- ineffective chain synthesis leading to ineffective erythropoiesis, hemolysis of RBCs and increase in HbF

Clinical Features
- initial presentation at age 6-12 mo when HbA normally replaces HbF
  - severe anemia, jaundice
  - stunted growth and development (hypogonadal dwarf)
  - gross hepatosplenomegaly (due to extramedullary hematopoiesis)
  - radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumours)
    - skull x-ray has “hair-on-end” appearance
    - pathologic fractures common
  - evidence of increased Hb catabolism (e.g. pigmented gallstones)
  - death can result from
    - untreated anemia (should transfuse)
    - infection (should identify and treat early)
    - iron overload: late complication secondary to repeated transfusions and ineffective erythropoiesis

Microcytosis in β-Thal Minor
Microcytosis is much more profound and the anemia is much milder than that of iron deficiency.
Hematology

Hemolytic Anemia (HA)

Investigations
- CBC: Hb 40-60 g/L (4-6 g/dL)
- Hb electrophoresis
  - HbA: 0-10% (normal >95%)  
  - HbA2 >2.5%  
  - HbF: 90-100%

Treatment
- lifelong regular transfusions to suppress endogenous erythropoiesis  
- iron chelation (e.g. deferoxamine, deferasirox, deferiprone) to prevent iron overload in organs and the formation of free radicals (which promote tissue damage and fibrosis)  
- folic acid supplementation if not transfused  
- allogenic bone marrow transplantation  
- splenectomy (now performed less frequently)

α-Thalassemia

Definition
- defect(s) in α genes  
- similar geographic distribution as β-thalassemia, but higher frequency among Asians and Africans

Clinical Features
- 1 defective α gene: clinically silent; normal Hb, normal MCV  
- 2 defective α genes: decreased MCV, normal Hb  
- 3 defective α genes: HbH (δ4) disease; presents in adults, decreased MCV, decreased Hb, splenomegaly  
- 4 defective α genes: Hb Barts (γ4) disease (hydrops fetalis); usually incompatible with life

Investigations
- peripheral blood film – screen for HbH inclusion bodies with special stain  
- Hb electrophoresis not diagnostic for α-thalassemia  
- DNA analysis using α gene probes is the only way to confirm the diagnosis

Treatment
- depends on degree of anemia:  
  - 1 or 2 defective α genes: no treatment required  
  - HbH disease: similar to β-thalassemia intermedia  
  - HbBarts: intrauterine transfusion

Sickle Cell Disease

Definition
- see Pediatrics, P48

Definition
- sickling disorders arise due to a mutant β-globin chain, most commonly caused by a Glu→Val substitution at position 6 (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)  
  - increased incidence of HbS allele with African or Mediterranean heritage (thought to be protective against malaria)  
- sickle cell disease occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant β-globin gene (compound heterozygote) – most commonly HbS-β-thal and HbSC disease

Pathophysiology (Figure 8)
- at low pO2, deoxy HbS polymerizes leading to rigid crystal-like rods that distort membranes  
  - ‘sickles’  
- the pO2 level at which sickling occurs is related to the percentage of HbS present  
  - heterozygotes (HbAS); sickling occurs at a pO2 of 40 mmHg  
  - homozygotes (HbSS); sickling occurs at a pO2 of 80 mmHg  
- sickling aggravated by acidemia, increased CO2, increased 2,3-DPG, fever and osmolality  
- fragile sickle cells hemolyze (nitric oxide depletion); they also occlude small vessels (ischemia-reperfusion injury)
Clinical Features
- HbAS (sickle cell trait): patient will be asymptomatic except during extreme hypoxia or infection
- increased risk of renal medullary carcinoma
- SCD-SS (HbSS)
  - chronic hemolytic anemia
  - jaundice in the first year of life
  - retarded growth and development ± skeletal changes
  - splenomegaly in childhood; splenic atrophy in adulthood
- SCD-SS often presents with acute pain episode:
  1. aplastic crises
  2. toxic crises (especially parvovirus B19) transiently suppress bone marrow
  3. vaso-occlusive crises (infarction)
  4. acute chest syndrome (see sidebar, H19)
- SCD-SC (most common compound heterozygote)
  1. 1,833 live births in African-Americans, common in West Africa
  2. milder anemia than HbSS
  3. similar complications as HbSS although typically milder and less frequent (exception is proliferative sickle retinopathy, glomerulonephritis and avascular necrosis)
  4. spleen not always atrophic in adults

Investigations
- sickle cell prep (detects sickling of RBCs under the microscope in response to O₂ lowering agent): determines the presence of a HbA allele, but does not distinguish HbAS from HbSS
- Hb electrophoresis distinguishes HbAS, HbSS, HbSC and other variants

### Table 13. Investigations for Sickle Cell Disease

<table>
<thead>
<tr>
<th></th>
<th>HbAS</th>
<th>HbSS</th>
</tr>

<tr>
<td>Hb electrophoresis</td>
<td>HbA fraction of 0.65 (65%)</td>
<td>No HbA, only HbS and HbF (proportions change with age), Normal amount of HbA2.</td>
</tr>
</tbody>
</table>

Treatment
- genetic counselling
- HbAS: no treatment required
- HbSC: treatment as per HbSS, but is dictated by symptom severity
- HbSS
  1. folic acid to prevent folate deficiency
  2. hydroxyurea to enhance production of HbF
  3. treatment of vaso-occlusive crisis
  4. prevention of crises

Long-Term Harms: Birth defects in offspring of people receiving the drug, growth delays in children, and cancer in both children and adults who receive the drug.

NIH Consensus Development Conference Statement: Hydroxyurea Treatment for Sickle Cell Disease

Am Intern Med 2008;148:932-938

Efficacy: Strong evidence for adolescents and adults and there is emerging data supporting its use in children. In the single RCT, the Hb level was higher in hydroxyurea recipients than placebo recipients after 2 yr (difference, 6 g/L), as was HbF (absolute difference, 3.2%). The median number of painful crises was 44% lower than in the placebo arm. The 12 observational studies that enrolled adults reported a relative increase in HbF of 4% to 20% and a relative reduction in crisis rates by 66% to 84%. Hospital admissions declined by 18% to 32%.

Effectiveness: Data is limited but seems to be highly effective but is currently underestimated.

Long-Term Harms: Birth defects in offspring of people receiving the drug, growth delays in children receiving the drug, and cancer in both children and adults who receive the drug.

Microangiopathic Hemolytic Anemia (MAHA)

Definition
- hemolytic anemia due to intravascular fragmentation of RBCs

Etiology
- thrombotic thrombocytopenic purpura (TTP)/hemolytic uremic syndrome (HUS), see H28
- disseminated intravascular coagulation (DIC), see H30
- eclampsia, HELLP syndrome, AFLP (see Obstetrics, OB17, OB19)
- malignant hypertension
- vasculitis
- malfunctioning heart valves
- metastatic carcinoma
- drugs (calcineurin inhibitors, quinine, simvastatin)
- infections (severe CMV or meningococcus)
- catastrophic antiphospholipid antibody syndrome

Investigations
- blood film: evidence of hemolysis, schistocytes
- hemolytic work-up
- urine: hemosiderinuria, hemoglobinuria

Hereditary Spherocytosis
- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
  - spleen makes defective RBCs more spherocytic (and more fragile) by membrane removal; also acts as site of RBC destruction
  - autosomal dominant with variable penetrance

Investigations
- blood film shows spherocytes, increased osmotic fragility, molecular analysis for spectrin gene

Treatment
- in severe cases, splenectomy + vaccination against pneumococcus, meningococcus and H. influenzae b (avoid in early childhood)

Hereditary Elliptocytosis

Definition/Etiology
- abnormality in spectrin interaction with other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild
Treatment
• immunizations; splenectomy for severe hemolysis

G6PD Deficiency

Definition
• deficiency in glucose-6-phosphate dehydrogenase (G6PD) leads to RBC sensitivity to oxidative stress due to a lack of reduced glutathione (GSH) (Figure 11)

Pathophysiology
• X-linked recessive, prevalent in individuals of African, Asian and Mediterranean descent

Clinical Features
• frequently presents as episodic hemolysis precipitated by:
  ▪ oxidative stress
  ▪ drugs (e.g. sulfonamide, antimalarials, nitrofurantoin)
  ▪ infection
  ▪ food (fava beans)
• in neonates: can present as prolonged, pathologic neonatal jaundice

Investigations
• neonatal screening
• G6PD assay (may not be useful if result is normal)
  ▪ should not be done in acute crisis when reticulocyte count is high (reticulocytes have high G6PD levels)
• blood film
  ▪ Heinz bodies (granules in RBCs due to oxidized Hb); passage through spleen results in the generation of bite cells
  ▪ may have features of intravascular hemolysis (e.g. RBC fragments)

Treatment
• folic acid
• stop offending drugs and avoid triggers
• transfusion in severe cases

Macrocytic Anemia

• MCV >100 fL
• see Figure 3, Approach to Anemia, H5

| Table 15. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia |
|----------------------------------|----------------------------------|----------------------------------|
| **Megaloblastic** | **Non-Megaloblastic** |
| **Morphology** | Large, oval, nucleated RBC precursor | Large round RBC |
| | Hypersegmented neutrophils | Normal neutrophils |
| **Pathophysiology** | Failure of DNA synthesis resulting in asynchronous maturation of RBC nucleus and cytoplasm | Reflects membrane abnormality with abnormal cholesterol metabolism |

Vitamin B12 Deficiency

B12 (cobalamin) see Gastroenterology, G17 and Family Medicine – Nutrition, FM5
• binds to intrinsic factor (IF) secreted by gastric parietal cells
• absorbed in terminal ileum
• total body stores sufficient for 3-4 yr

Etiology

| Table 16. Etiology of Vitamin B12 Deficiency |
|-----------------------------------------------|-----------------------------------------------|-----------------------------------------------|
| **Diet** | **Gastric** | **Intestinal Absorption** | **Genetic** |
| Strict vegan | Mucosal atrophy | Malabsorption | Transcobalamin II deficiency |
| More likely to present in pediatric population | Gastritis, autoimmune | Crohn's, celiac sprue, pancreatic insufficiency |
| Vegetarian in pregnancy | Pernicious anemia (see H23) | Stagnant bowel | |
| Post-gastrectomy | | Blind loop, stricture |
| | | Fish tapeworm |
| | | Resection of ileum |
| | | Drugs |
| | | Neomycin, biguanides, PPI, N2O anesthesia |
Pathophysiology of Pernicious Anemia

- auto-antibodies produced against gastric parietal cells leading to achlorhydria and lack of intrinsic factor secretion
- intrinsic factor is required to stabilize B₁₂ as it passes through the bowel
- decreased intrinsic factor leads to decreased ileal absorption of B₁₂
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- female:male = 1.6:1; often >60 yr old

Clinical Features

- neurological
  - cerebral (common, reversible with B₁₂ therapy)
  - confusion, delirium, dementia
  - cranial nerves (rare)
  - optic atrophy
  - cord (irreversible damage)
  - subacute combined degeneration
    - posterior columns: decreased vibration sense, proprioception and 2-point discrimination
    - pyramidal tracts: spastic weakness, hyperactive reflexes
  - peripheral neuropathy (variable reversibility)
  - usually symmetrical, affecting lower limbs more than upper limbs

Investigations

- CBC, reticulocyte count
- anemia often severe ± neutropenia ± thrombocytopenia
- MCV >110 fL
- low reticulocyte count relative to the degree of anemia (<2%)
- serum B₁₂ and RBC folate
  - caution: low serum B₁₂ leads to low RBC folate because of failure of folate polyglutamate synthesis in the absence of B₁₂
  - alternatively, can measure urine metabolites (methylnalenate, homocysteine)
- blood film
  - oval macrocytes, hypersegmented neutrophils
- bone marrow
  - hypercellularity
  - nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from the development of the cytoplasm)
- bilirubin and LDH
  - elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
- Schilling test (see sidebar) to distinguish pernicious anemia from other causes
  - anti-intrinsic factor antibody, anti-parietal cell antibody

Treatment

- vitamin B₁₂ 1000 µg IM monthly for life or 1000-1200 µg PO daily if intestinal absorption intact
- less frequent, higher doses may be as effective (e.g. 1000 µg IM q3mo)
- watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

Folate Deficiency

- uncommon in developed countries due to extensive dietary supplementation
- folate stores are depleted in 3-6 mo
- folate commonly found in green, leafy vegetables and fortified cereals

Etiology

<table>
<thead>
<tr>
<th>Diet/Deficiency</th>
<th>Malabsorption</th>
<th>Drugs</th>
<th>Increased Demand</th>
</tr>
</thead>
<tbody>
<tr>

<td>Short bowel syndrome</td>
<td>Oral contraceptive</td>
<td>Exfoliative dermatitis/psoriasis</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Hemodialysis</td>
</tr>
</tbody>
</table>

Clinical Features

- mild jaundice due to hemolysis of RBCs secondary to ineffective hemoglobin synthesis
- glossitis and angular stomatitis
- melanin pigmentation (rare)
- purpura secondary to thrombocytopenia (rare)
- unlike B₁₂ deficiency, folate deficiency has no neurologic manifestations
Investigations
- similar to $B_12$ deficiency (CBC, reticulocytes, blood film, RBC folate, serum $B_12$)
- if decreased RBC folate, rule out $B_12$ deficiency as cause

Management
- folic acid 1-5 mg PO OD x 1-4 mo; then 1 mg PO OD maintenance if cause is not reversible

Hemostasis

Three Phases of Hemostasis

1. Primary Hemostasis
- goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
- vessel injury results in collagen/subendothelial matrix exposure and release of vasoconstrictors
- blood flow is impeded and platelets come into contact with damaged vessel wall (Figure 12a)
  - adhesion: platelets adhere to subendothelium via von Willebrand factor (vWF)
  - activation: platelets are activated resulting in change of shape and release of ADP and thromboxane $A_2$
  - aggregation: these factors further recruit and aggregate more platelets resulting in formation of localized hemostatic plug

2. Secondary Hemostasis
- platelet plug is reinforced by production of fibrin clot in secondary hemostasis (Figure 12b)
  - extrinsic pathway
    - initiation of coagulation in vivo
  - intrinsic pathway
    - amplification once coagulation has started

3. Fibrin Stabilization and Fibrinolysis (resolution)
- conversion from soluble to insoluble clot
- once healing initiated, clot dissolution (anticoagulant pathway)
### Table 18. Commonly Used Tests of Hemostasis

### Disorders of Primary Hemostasis

**Definition**
- inability to form an adequate platelet plug due to:
  - disorders of blood vessels
  - disorders of platelets
    - abnormal function
    - abnormal numbers (thrombocytopenia)
  - disorders of vWF
Classification

1. Hemostasis Disorders

- Platelets
  - Low platelet count: Thrombocytopenia (see H6)
  - Normal platelet count: Platelet dysfunction
- vWD
- Acquired

Decreased production: Aplastic anemia
Increased destruction: ITP
Sequestration: Splenomegaly
Hereditary
- Bernard Soulier syndrome (GP1b deficiency)
- Glanzmann syndrome (GP IIb/IIIa deficiency)
Acquired
- Purpura simplex (easy bruising)
- Sickle purpura
- Dysproteinemias
- HSP
- Scurvy
- Cushing’s syndrome
- Infections, drugs

CRF = chronic renal failure; HSP = Henoch-Schönlein purpura

Figure 14. Approach to disorders of primary hemostasis

</tbody>
</table>

**ACUTE (CHILD-TYPE) ITP**
- see Pediatrics, P49

**CHRONIC (ADULT-TYPE) ITP**
- most common cause of isolated thrombocytopenia
- diagnosis of exclusion [i.e. isolated thrombocytopenia (platelets <100 x 10^9/L) and the absence of any obvious initiating and/or underlying cause]

**Pathophysiology**
- an acquired immune-mediated disorder with:
  - anti-platelet antibodies bind to platelet surface → increased splenic destruction and clearance
  - impaired platelet production
  - helper T-cell and cytotoxic T-cell activation also implicated in platelet destruction

**Clinical Presentation**
- can present with no symptoms, minimal bruising to a serious bleed (including GI bleed, skin and mucosal hemorrhage or intracranial hemorrhage), lethargy, fatigue

**Investigations**
- CBC and reticulocyte count: thrombocytopenia (request retic count if not an isolated thrombocytopenia)
- PT and aPTT: normal
- peripheral blood film: decreased platelets, giant platelets (to rule out platelet clumping)
- HIV, HCV (if risk factors are present)
- bone marrow aspirate and biopsy: increased number of megakaryocytes
- recommended in patients >60 yr of age, pre-splenectomy or have failed multiple lines of ITP treatment, those with systemic symptoms, an abnormal blood film and/or abnormal signs to rule out other causes of thrombocytopenia (e.g. myelodyplasia)

**Mechanisms for HIV-associated Thrombocytopenia**
- Direct effect of HIV on marrow
- Immune-mediated platelet destruction
- Some antiretrovirals reduce platelet production

**Drugs Associated with Thrombocytopenia**

**Should Rituximab be Used Before or After Splenectomy in Patients with Immune Thrombocytopenic Purpura (ITP)?**

**Curr Opin Hematol** 2007;14(4):42-46

**Purpose:** To determine whether the optimal timing for rituximab is before splenectomy, or after failure of splenectomy.

**Results:** Rituximab produces an initial response in approximately 60% of cases, with no significant difference between splenectomized and non-splenectomized patients. Long-term complete responses are observed in 15-20% of cases. Adverse events related to the drug were usually mild or moderate, with a low incidence of infections. Long-term safety data, however, are still lacking. Deaths have been reported for 2.9% of ITP cases treated with rituximab, but they could not be attributed to the study drug.

**Conclusion:** Both the response rate and the response duration appear lower following rituximab than following splenectomy. Although the side effects may be fewer, there is insufficient evidence to support the replacement of splenectomy with rituximab as a second-line treatment of chronic ITP outside a clinical trial. At the present time, the use of immunotherapy before splenectomy can be recommended only in patients at high risk for splenectomy and in those not willing to undergo surgery.
Heparin-Induced Thrombocytopenia (HIT) (Previously Known as HIT Type II)

**Pathophysiology**
- Immune mediated
  - Ab recognizes a complex of heparin and platelet factor 4 (PF4) leading to platelet activation via platelet Fc receptor and activation of coagulation system

**Diagnosis**
- 50% reduction in platelets while on heparin within 5-15 wk of initiation

**Onset of Decreased Platelets**
- 5-15 wk (if previously exposed to heparin, HIT can develop in hours)

**Risk of Thrombosis**
- ~30% (25% of events are arterial)

**Clinical Features**
- Bleeding complications uncommon
  - Venous thrombosis: DVT, PE, limb gangrene, cerebral sinus thrombosis
  - Arterial thrombosis: MI, stroke, acute limb ischemia, organ infarct (mesentery, kidney)
  - Heparin-induced skin necrosis (with LMWH)
  - Acute platelet activation syndromes: acute inflammatory reactions (e.g. fever/chills, flushing, etc.)
  - Transient global amnesia (rare)

**Specific Tests**
- 
  - $^{14}$C serotonin release assay (uses donor platelets with $^{14}$C serotonin and heparin with patient’s plasma)
  - ELISA for HIT-Ig (more sensitive, less specific than serotonin assay)
  - Ultrasound of lower limb veins for DVT

**Management**
- Clinical suspicion of HIT should prompt discontinuation of heparin (specific tests take several days)
  - Because of 90% cross-reactivity, LMWH should not be substituted
  - Alternative agents include: Argatroban (effective thrombin inhibitor, monitored with aPTT, use with caution in liver disease), fondaparinux (treatment dose, not prophylaxis)

**Prognosis**
- ~20% will not attain a hemostatic platelet count after first and second line therapy
- Fluctuating course
- Overall relatively benign, mortality 1-2%, (2X higher mortality than the unaffected population)
- Major concern is cerebral hemorrhage at Plt <5 x 10^9/L, although very rare

**Evaluation of Pretreatment Clinical Score (4 Ts) for the Diagnosis of Heparin-induced Thrombocytopenia in Two Clinical Settings**
*J Thromb Haemos 2006;4:759-1765*

Study: Prospective and retrospective clinical score application in two clinical settings (Hamilton General Hospital, HGH; and Greifswald in Germany, GW).

Population: 336 patients with suspected HIT.

Intervention: Risk stratification with a 4Ts clinical score compared with serology for HIT antibody.

Results: 1/64 (1.6%) in HGH and 0/55 (0%) in GW with low scores tested positive on HIT serology, 9/28 (32.1%) in HGH and 11/139 (7.9%) in GW with intermediate scores tested positive for HIT, 8/8 (100%) in HGH and 9/42 (21.4%) in GW with high scores tested positive for HIT.

Conclusion: A low pretreatment clinical score can help to rule out HIT in patients with thrombocytopenia.

Heparin-Induced Thrombocytopenia (HIT) is a rare and potentially serious complication of heparin therapy, characterized by the development of thrombocytopenia associated with the administration of heparin. It is divided into two subtypes based on its pathogenesis: immune-mediated HIT and non-immune-mediated HIT.

### Clinical Features
- **Bleeding complications:** Uncommon, but can include venous thrombosis (DVT, PE), limb gangrene, cerebral sinus thrombosis, arterial thrombosis (MI, stroke), acute limb ischemia, organ infarct (e.g., mesentery, kidney), and heparin-induced skin necrosis (with LMWH).
- **Acute platelet activation syndromes:** These can manifest as acute inflammatory reactions such as fever, chills, flushing, etc., and transient global amnesia.

### Specific Tests
- **$^{14}$C serotonin release assay:** Uses donor platelets with $^{14}$C serotonin and patient’s plasma.
- **ELISA for HIT-Ig:** More sensitive than the serotonin assay.
- **Ultrasound of lower limb veins for DVT:** To rule out other causes of thrombosis.

### Management
- **Clinical suspicion of HIT:** Prompt discontinuation of heparin (specific tests may take several days).
- **Alternative agents:** Argatroban (effective thrombin inhibitor, monitored with aPTT), fondaparinux (treatment dose, not prophylaxis).

### Prognosis
- Typically, HIT carries a relatively benign prognosis overall, with a mortality rate of 1-2% (2X higher than the unaffected population).
- However, a major concern is cerebral hemorrhage, especially in patients with platelet counts below 5 x 10^9/L.

### Preventive Measures
- **Avoidance of 4 Ts makes HIT unlikely:**
  - **Thrombocytopenia:** Timing of platelet count fall
  - **Thrombosis or other sequelae:** Other causes for thrombocytopenia

LMWH is also associated with HIT, but the risk is less than unfractionated heparin (2.8% in UFH vs. 0.2% in LMWH).

Heparin-associated thrombocytopenia (previously known as HIT type I)
- **Direct heparin-mediated platelet aggregation (non-immune):**
- **Platelets > 100 x 10^9/L:**
- **Self-limited (no thrombotic risk):**
- **May continue with heparin therapy:**
- **Onset 24-72 h**
**Thrombotic Thrombocytopenic Purpura (TTP) and Hemolytic Uremic Syndrome (HUS)**

**Von Willebrand Disease (vWD)**

**Pathophysiology**
- heterogeneous group of defects
- usually autosomal dominant (type 3 is autosomal recessive)
- qualitative or quantitative abnormality of vWF
  - vWF needed for platelet adhesion and acts as carrier for Factor VIII; abnormality of vWF can affect both primary and secondary hemostasis
  - vWF exists as a series of multimers ranging in size
    - largest multimers are most active in mediation of platelet adhesion
    - both large and small multimers complex with Factor VIII
- usually mild in severity

**Classification**
- type 1: mild quantitative defect (decreased amount of vWF and proportional decrease in vWF activity) – 75% of cases
- type 2: qualitative defect (vWF activity disproportionally lower than quantity) – 20-25% of cases
- type 3: severe total quantitative defect (no vWF produced) – rare

**Clinical Features**
- mild
  - asymptomatic
  - mucosal and cutaneous bleeding, easy bruising, epistaxis, menorrhagia
- moderate to severe
  - as above but more severe, occasionally soft-tissue hematomas, petechiae (rare), GI bleeding, hemarthroses

**Investigations**

**Notes:**
- Consider vWD in all women with menorrhagia.
Hematology Disorders of Primary Hemostasis/Disorders of Secondary Hemostasis Toronto Notes 2014

Treatment
• desmopressin (DDAVP+) is treatment of choice for type 1 vWD
  ▫ causes release of vWF and Factor VIII from endothelial cells
  ▫ variable efficacy depending on disease type; tachyphylaxis occurs
  ▫ need good response before using with further bleeding
  ▫ caution in children due to hyponatremia
• tranexamic acid (Cyklokapron®, antifibrinolytic) to stabilize clot formation
• high-purity Factor VIII concentrate containing vWF (Hemate P®) in select cases and type
  ▫ frozen plasma (FP) is not useful
  ▫ need to monitor vWF and factor VIII levels (very high factor VIII level can cause thrombosis)
• conjugated estrogens (increase vWF levels)

Prognosis
• may fluctuate, often improves during pregnancy, inflammation and with age

Disorders of Secondary Hemostasis

Definition
• inability to form an adequate fibrin clot
  ▫ disorders of clotting factors or co-factors
  ▫ disorders of proteins associated with fibrinolysis
  ▫ characterized by delayed bleeding, deep muscular bleeding, spontaneous joint bleeding

Hemophilia A (Factor VIII Deficiency)

Pathophysiology
• X-linked recessive, 1/5,000 males
• mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

Clinical Features
• see Table 19 – Signs and Symptoms of Disorders of Hemostasis, H25
• older patients may also have HIV or HCV from contaminated blood products

Investigations
• prolonged aPTT, normal INR (PT)
• decreased Factor VIII (<40% of normal)
• vWF usually normal or increased

Treatment
• desmopressin (DDAVP+) in mild hemophilia A
• recombinant Factor VIII concentrate for
  ▫ prophylaxis (2-3 times a week at home)
  ▫ minor but not trivial bleeding (e.g. hemarthroses)
  ▫ major potentially life-threatening bleeding (e.g. multiple trauma)
• anti-fibrinolytic agents (e.g. tranexamic acid)

Hemophilia B (Factor IX Deficiency)

• aka Christmas disease
• X-linked recessive, 1/30,000 males
• clinical and laboratory features identical to hemophilia A (except decreased Factor IX)
• treatment: recombinant Factor IX concentrate, anti-fibrinolytic agents

Factor XI Deficiency

• aka Rosenthal syndrome
• autosomal recessive; more common in Ashkenazi Jews
• usually mild, often diagnosed in adulthood
• Factor XI level does not correlate with bleeding risk
• treatment: frozen plasma, Factor XI concentrate
Liver Disease

- see Gastroenterology, G28

Pathophysiology
- deficient synthesis of all factors except VIII (also made in endothelium and in acute phase response)
- aberrant synthesis of fibrinogen
- deficient clearance of hemostatic ‘debris’ and fibrinolytic activators
- accelerated destruction due to dysfibrinogenemias: increased fibrinolysis, DIC
- miscellaneous: inhibition of secondary hemostasis by FDPs

Investigations
- peripheral blood film: target cells
- primary hemostasis affected
  - thrombocytopenia due to hypersplenism, folate deficiency, alcohol intoxication, DIC, decreased production of thrombopoietin
  - platelet dysfunction (e.g. alcohol abuse)
- secondary hemostasis affected
  - elevated INR (PT), aPTT and TT, low fibrinogen in end-stage liver disease

Treatment
- supportive, treat liver disease, blood products if active bleeding (frozen plasma, platelets, cryoprecipitate)

Vitamin K Deficiency

Etiology
- drugs
  - oral anticoagulants which inhibit Factors II, VII, IX, X, proteins C and S
  - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet (especially in alcoholics)
- biliary obstruction
- chronic liver disease (decreased stores)
- malabsorption (e.g. celiac disease)
- hemorrhagic disease of newborn, see Pediatrics, P71

Investigations
- INR (PT) is elevated out of proportion to elevation of the aPTT
- decreased Factors II, VII, IX and X (vitamin K-dependent)

Treatment
- hold anticoagulant
- vitamin K 1 mg PO for INR between 4.5 and 10 and no active bleeding (excludes hemorrhagic disease of the newborn)
- if bleeding, give vitamin K 10 mg IV
- if life-threatening bleeding and vitamin K antagonist use, give frozen plasma or prothrombin complex concentrate (PCC)
  - PCCs are contraindicated if there is a previous history of HIT
  - use FFP if PCC is contraindicated or unavailable
- note: excessive vitamin K will delay therapeutic warfarin anticoagulation once re-started

Disseminated Intravascular Coagulation (DIC)

- see also Obstetrics, OB21

Definition
- uncontrolled release of plasmin and thrombin leading to intravascular coagulation and depletion of platelets, coagulation factors and fibrinogen
- risk of life-threatening hemorrhage

Etiology
- occurs as a complication of many other conditions
- widespread endothelial damage ± extensive inflammatory cytokine release

DIC is a spectrum which may include thrombosis, bleeding or both.
Clinical Features
• presence of both hemorrhage and clotting

Table 27. Clinical Features of DIC

<table>
<thead>
<tr>
<th>Signs of Microvascular Thrombosis</th>
<th>Signs of Hemorrhagic Diathesis</th>
</tr>
</thead>
<tbody>

<td>Muscosal: gingival oozing, epistaxis, massive bleeding</td>
</tr>
</tbody>
</table>

Investigations
• primary hemostasis: decreased platelets
• secondary hemostasis: prolonged INR (PT), aPTT, TT, decreased fibrinogen and other factors
• fibrinolysis: increased FDPs or D-dimers, short euglobulin lysis time (i.e. accelerated fibrinolysis)
• extent of fibrin deposition: urine output, urea, RBC fragmentation

Treatment
• recognize early
• treat underlying disorder
• individualized critical care support
• in hemorrhage: replacement of hemostatic elements with platelet transfusion, frozen plasma, cryoprecipitate
  ▪ maintain platelets >50 x10⁹ and hemoglobin >80 g/L
  ▪ 4-5 units of FFP if INR >1.5 or aPTT >38
  ▪ 10 units of cryoprecipitate if fibrinogen <1 g/L
• 1 adult dose of buffy-coat platelets if <10 x10⁹ (<20 if febrile, <50 before invasive procedure)
• in thrombotic phase: UFH or LMWH in critically ill, non-bleeding patients

Venous Thromboembolism

Definition
• thrombus formation and subsequent inflammatory response in a superficial or deep vein
• superficial thrombophlebitis, deep vein thrombosis (DVT) and pulmonary embolism (PE)
• thrombi propagate in the direction of blood flow (commonly originating in calf veins)
• more common in lower extremity than upper extremity
• incidence ~1% if age >60 yr
• most important sequelae are pulmonary embolism (~50% chance with proximal DVT) and chronic venous insufficiency
Etiology (Virchow’s Triad)

- endothelial damage
  - exposes endothelium to prompt hemostasis
  - leads to decreased inhibition of coagulation and local fibrinolysis
- venous stasis
  - immobilization (post-MI, CHF, stroke, post-op) inhibits clearance and dilution of coagulation factors
- hypercoagulability
  - inherited (see Hypercoagulable Disorders, H34)
  - acquired
    - age (risk increases with age)
    - surgery (especially orthopedic, thoracic, GI and GU)
    - trauma (especially fractures of spine, pelvis, femur or tibia, spinal cord injury)
    - neoplasms (especially lung, pancreas, colon, rectum, kidney and prostate)
    - blood dyscrasias (myeloproliferative neoplasms, especially PV, ET), PNH, hyperviscosity
      (multiple myeloma, polycythemia, leukemia, sickle cell disease)
    - prolonged immobilization (CHF, stroke, MI, leg injury)
    - hormone related (pregnancy, OCP, HRT, SERMs)
    - APS
    - heart failure (risk of DVT greatest with right heart failure and peripheral edema)
- idiopathic (10-20% are later found to have cancer)

Clinical Features of DVT

- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth and tenderness
- palpable cord (thrombosed vein)
- phlebitis or varicose veins
- leg swelling in deep veins
- calf pain or swelling
- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency
- tenderness (knee, ankle, posterior tibial arch)
- sites of phlebitis (femoral, iliac, popliteal)
- Pitting edema greater in the calf than in the thigh
- calf tenderness on palpation
- calf swelling > 3 cm than other leg
- localized tenderness in deep vein system
- Swelling of entire leg
- Calf swelling > 3 cm than other leg
- recent major trauma
- brain metastases
- muscle damage (proximal, distal)
- muscle weakness
- increased muscle tone
- postural hypotension
- weight loss
- fever
- acute onset
- recent neurosurgery or ocular surgery within 10 d
- active cancer
- recent major surgery within past 4 wk
- localized tenderness in deep vein system
- recent stroke

Differential Diagnosis of DVT

- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency, ruptured popliteal cysts, cellulitis, arterial occlusive disease

Investigations for DVT

- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease and no other acute medical issues/recent surgery
- doppler ultrasound is most useful diagnostic test for DVT
  - sensitivity and specificity for proximal DVT ~95%
  - sensitivity for calf DVT ~70%
- other non-invasive tests include MRI and impedance plethysmography
- venography is the gold standard, but is expensive, invasive and higher risk
- for Clinical Features and Treatment of PE, see Respirology, R17

Approach to Treatment of Venous Thromboembolism (VTE)

Purpose

- prevent further clot extension
- prevent acute pulmonary embolism (occurs in up to 50% of untreated patients)
- reduce the risk of recurrent thrombosis
- treatment of massive iliofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlebitis cerulea dolens)
- limit development of late complications, e.g. postphlebitic syndrome, chronic venous insufficiency and chronic thromboembolic pulmonary HTN

Absolute Contraindications to Treatment

- active bleeding
- severe bleeding diathesis or platelet count <20 x 10^9/L (<20,000/mm^3)
- intracranial bleeding
- neurosurgery or ocular surgery within 10 d

Relative Contraindications to Treatment

- mild-moderate bleeding diathesis or thrombocytopenia
- brain metastases
- recent major trauma
- major abdominal surgery within the past 2 d
- GI or GU bleeding within 14 d
- endocarditis
- severe hypertension (sBP >200 or dBP >120)
- recent stroke
Initial Treatment
- low molecular weight heparin (LMWH)
  - administered SC, at least as effective as UFH with a lower bleeding risk
  - advantages: predictable dose response and fixed dosing schedule; lab monitoring not required; <1% HIT; safe and effective outpatient therapy
  - disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis
  - renally cleared – must adjust dose in patients with renal dysfunction
- unfractionated heparin (UFH)
  - in patient with average risk of bleed; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
  - advantages: rapidly reversible by protamine
  - disadvantages: must monitor aPTT with adjustment of dose to reach therapeutic level (~2x normal value); monitor platelet counts for development of HIT
- alternatives to LMWH and UFH
  - heparinoids (patients with HIT), direct thrombin inhibitors (hirudin, lepirudin, argatroban, dabigatran), Factor Xa inhibitors (fondaparinux, rivaroxaban)
  - thrombolytic drugs (e.g. streptokinase, tPA) reserved for acute limb/life-threatening thrombosis, and low bleeding risk

Long-term Treatment
- warfarin:
  - standard treatment; should be initiated with heparin overlap: dual therapy for at least 5 d, due to initial prothrombotic state, half life of vitamin K factors and risk of warfarin-induced skin necrosis
  - discontinue heparin after INR >2.0 for two consecutive days
  - warfarin should be dosed to maintain INR at 2-3 except in select cases
  - monitor INR twice weekly for 1-2 wk, then weekly until INR stable, then every 2-4 wk
  - LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients (see sidebar, H32)
- duration of anticoagulant treatment (with warfarin unless otherwise noted):
  - first episode DVT with no identifiable risk factor (idiopathic) or single inherited risk factor (e.g. Factor V Leiden): 6-12 mo or indefinite therapy (controversial)
  - recurrent DVT (2 or more episodes): indefinite therapy
  - IVC filters:
    - temporary filter indicated only if distal acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e. active bleeding)
    - must remove once safe to do so as filter is pro-thrombotic in the longterm (anticoagulation if left in)
  - special considerations
    - pregnancy: treat with LMWH during pregnancy, then warfarin for 4-6 wk post-partum (minimum total anticoagulation time of 3-6 mo)
    - surgery: avoid elective surgery in the first month after a venous or arterial thromboembolic event
      - preoperatively: IV heparin may be used up to 6 h pre-operatively
      - perioperatively: surgery safe when INR <1.5; warfarin should be discontinued for at least 4 wk pre-operatively to allow INR to fall
      - postoperatively: IV heparin or LMWH can be used for anticoagulation (start 12 h after major surgery until therapeutic INR reached after restarting warfarin)
      - for patients at high risk for thromboembolism (VTE <12 wk, recurrent VTE, lupus anticoagulant, atrial fibrillation with prior stroke, mechanical heart valve), IV heparin or LMWH (bridging) should be given before and after the procedure while the INR is below 2.0

Prophylaxis
- see sidebar
- consider for those with a moderate to high risk of thrombosis without contraindications
- non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), intermittent pneumatic compression (IPC)
- UFH 5000 IU SC bid for moderate risk
- UFH 5000 IU SC tid or LMWH as per hospital protocol (i.e. enoxaparin 40 mg SC daily) or UFH 5000 IU SC tid for high risk

Contraindications and Adverse Reactions of Anticoagulant Therapy
- absolute: active bleeding, severe bleeding diathesis or platelets <20 x 10^9/L (<20,000/mm³), intracranial bleeding, neuro or ocular surgery within <10 d
- relative: mild-moderate neurologic diathesis or thrombocytopenia, brain metastases, recent major trauma, major abdominal surgery within page 2 d, GI/GU bleed within 14 d, endocarditis, severe HTN (SBP >200 or DBP >120), recent stroke

Treatment of Pulmonary Embolism (PE)
- see Respirology, R19

Duration of Treatment with Vitamin K Antagonists in Symptomatic Venous Thromboembolism
- Cochrane GB Spor Rev 2006;1:C0001367
- Study: Meta-analysis of 8 RCTs (2994 patients) comparing different durations of treatment with vitamin K antagonists in patients with symptomatic venous thromboembolism (VTE).
- Main Results: In patients treated with vitamin K antagonists for a prolonged period, the reduction in risk of recurrent VTE remained consistent regardless of the period of time since the index event (OR 0.89, CI 0.53-1.50). In addition, there was no observed excess of VTE recurrences following cessation of prolonged vitamin K, antagonist therapy (OR 1.24, CI 0.87-1.79). However, patients who received prolonged treatment had a persistent increase in their risk of major bleeding complications (OR 2.61, CI 1.48-4.61).
- Conclusion: Prolonged treatment with vitamin K antagonists leads to a consistent reduction in the risk of recurrent VTE that is maintained over time. The absolute risk of recurrent VTE (which remains constant over time) is of greater concern than the absolute risk of major bleeding complications (which declines over time). No specific recommendation was made regarding optimal duration of treatment.

Common Medications that Interact with Warfarin
- Acetaminophen (interference with vit K metabolism)
- Allopurinol
- NSAIDs (GI injury)
- Fluconazole
- Metronidazole
- Sulfamethoxazole
- Tamoxifen

Initiation of Warfarin Therapy Requires Overlap with Heparin Therapy for 4-5 Days
- 10 mg loading dose of warfarin causes a precipitous decline in protein C levels in first 36 h resulting in a transient hypercoagulable state.
- Warfarin decreases Factor VII levels in first 48 h INR is prolonged (most sensitive to Factor VII levels), however full antithrombotic effect is not achieved until Factor IX, X, and II are sufficiently reduced (occurs after approx. 4 d).

Low risk surgical patients:
- <40 yr, no risk factors for VTE, general anesthetic (GA) <30 min, minor elective, abdominal or thoracic surgery.
- Moderate risk surgical patients:
  - >40 yr, >1 risk factor for VTE, GA >30 min.
- High risk surgical patients:
  - >40 yr, surgery for malignancy or lower extremity orthopedic surgery lasting >30 min, inhibitor deficiency or other risk factor.
- High risk medical patients: heart failure, severe respiratory disease, ischemic stroke and lower limb paralysis, confined to bed and have >1 additional risk factor (e.g. active cancer, previous VTE, sepsis, acute neurologic disease, IBD).

Toronto Notes 2014
Hypercoagulability Workup – Venous Thrombosis
- workup for malignancy or hypercoagulable state indicated for idiopathic VTE in presence of the following: age <50, recurrent VTE, family history of VTE and age <50, unusual site of DVT (portal, hepatic, mesenteric vascular beds), heparin-resistant disease (AT deficiency), warfarin-induced skin necrosis or neonatal purpura fulminans (proteins C or S deficiency). Consider for women with VTE within 12 mo of exposure to OCP
- workup:
  - initial
    - CBC, blood smear, coagulation studies, liver/renal function, urinalysis, fasting homocysteine
    - malignancy work up (see sidebar)
    - anti-phospholipid antibodies (APLA): anticardiolipin antibodies (ACA) and lupus anticoagulant (LA)
    - activated protein C resistance (APCR)
    - DNA: FVL (Factor V Leiden), PT (prothrombin G20210A)
  - post initial insult (>72 h) as protein levels depleted/consumed by clot
    - antithrombin (not on heparin)
    - Factor VIII (increased levels predict recurrence)
  - post-treatment
    - proteins C, S (not on warfarin)
- Note: most of these tests do not change management, and a negative test does not rule out a hypercoagulable state. Thus more focus is on the reversible/treatable causes (APLA, cancer, etc.)

CAUSES OF HYPERCOAGULABILITY LEADING TO VENOUS THROMBOEMBOLISM

Activated Protein C Resistance (Factor V Leiden)
- most common cause of hereditary thrombophilia
- 5% of general population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

Prothrombin (PT) G20210A
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

Protein C and Protein S Deficiency
- protein C inactivates Factor Va and VIIIa using protein S as a cofactor
- protein C deficiency
  - homozygous: neonatal purpura fulminans
  - heterozygous:
    - type I: decreased protein C levels
    - type II: decreased protein C activity
  - acquired: liver disease, sepsis, DIC, warfarin
  - 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
  - type I: decreased free and total protein S levels
  - type II: decreased protein S activity
  - type III: decreased free protein S levels
  - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, warfarin

Antithrombin Deficiency
- antithrombin slowly inactivates thrombin in the presence of heparin, rapidly inactivates thrombin in the presence of heparin
- autosomal dominant inheritance or urinary losses in nephrotic syndrome
  - type I: decreased AT levels
  - type II: decreased AT activity
- diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
- deficiency may result in resistance to unfractionated heparin (LMWH must be used)

Elevated Factor VIII Levels
- an independent marker of increased thrombotic risk
- genetic basis for increased levels poorly understood

Disorders of Fibrinolysis
- include congenital plasminogen deficiency, tissue plasminogen activator deficiency

Antiphospholipid Antibody Syndrome (APS)
- definition: ≥1 clinical and ≥1 laboratory criteria
  - clinical: thrombosis, spontaneous abortions, fetal loss, premature birth before 34 wk
  - laboratory: anticardiolipin or lupus anticoagulant antibodies
- mechanism: not well understood, antibodies interact with platelet membrane phospholipid causing increased adhesion and aggregation; can also interfere with action of proteins C and S
- see Rheumatology, RH12
Acute Myeloid Leukemia (AML)

Definition
- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

Epidemiology
- incidence increases with age; median age of onset is 65 yr old
- accounts for 10-15% of childhood leukemias

Risk Factors
- myelodysplastic syndromes (MDS), benzene, radiation, alkylating agents as treatment for previous malignancy

Pathophysiology
- etiology subdivided into:
  - primary: de novo
  - secondary: hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to:
  - suppression of normal hematopoietic cells
  - appearance of blasts in peripheral blood
  - accumulation of blasts in other sites (e.g. skin, gums)
  - metabolic consequences; tumour lysis syndrome

Clinical Features
- anemia, thrombocytopenia (associated with DIC in PML), neutropenia (even with normal WBC), leads to infections, fever
- thrombocytopenia (associated with DIC in promyelocytic leukemia)
- accumulation of blast cells in marrow
  - skeletal pain, bony tenderness (especially sternum)
- organ infiltration
  - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
  - hepatosplenomegaly (in ALL)
  - lymphadenopathy (not marked)
  - skin: leukemia cutis
  - gonads (in ALL)
  - eyes: Roth spots, cotton wool spots, vision changes (uncommon)
- leukostasis/hyperleukosisis syndrome (medical emergency)
  - large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, priapism

Typical Age of Presentation of Leukemias
- ALL: Children and older adults
- CML: 40-60 yr
- AML, CLL: >60 yr

Leukemia: malignant cells arise in bone marrow and may spread elsewhere (including blood, lymph nodes and lymphoid tissue).

Lymphoma: malignant cells arise in lymph nodes and lymphoid tissues and may spread elsewhere (including blood and bone marrow).

BUT the location where the malignant cells are found does not solely define the type of hematologic malignancy – classified based on the characteristics of the cell (histology, histochemistry, immunophenotyping, cytogenetics, molecular changes).
• metabolic effects; aggravated by treatment (rare)
  - increased uric acid → nephropathy, gout
  - release of phosphate → decreased Ca\(^{2+}\), decreased Mg\(^{2+}\)
  - release of procoagulants → DIC (higher risk in acute promyelocytic leukemia)
  - decreased or normal K\(^{+}\) before treatment, increased K\(^{+}\) after treatment

Investigations

- bloodwork:
  - CBC: anemia, thrombocytopenia, variable WBC
  - INR, aPTT, fibrin degradation products (FDP), fibrinogen (in case of DIC)
  - increased LDH, increased uric acid, increased PO\(_4^{3-}\) (released by leukemic blasts), decreased Ca\(^{2+}\)
  - baseline renal and liver function tests
- peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
- bone marrow aspirate:
  - blast count: AML >20% (normal is <5%)
  - morphologic, cytochemical and/or immunotypic features are used to establish lineage and maturation (see sidebar for WHO classification of AML, H35)
- CXR to r/o pneumonia, ECG, MUGA scan prior to chemotherapy (cardiotoxic)

Treatment

- mainstay of treatment is chemotherapy (rapidly fatal without treatment)
  - all AML subtypes treated similarly except promyelocytic variant with t(15:17) translocation
    - all-trans-retinoic acid (ATRA) added to induce differentiation
- treatment strategy:
  1. Induction: chemotherapy to induce complete remission of AML (see sidebar)
    - several possible regimens [e.g. cytarabine with anthracycline (daunorubicin)]
    - patients with poor response to initial induction therapy – worse prognosis
    - must ensure reversal of DIC, platelet transfusions if <10
  2. Consolidation: to prevent recurrence
    - intensive consolidation chemotherapy
    - stem cell transplantation – autologous or allogeneic (younger patients with better performance status)
- consider acceleration with hematopoietic growth factors (e.g. G-CSF) if severe infection develops
- supportive care
  - screening for infection via regular C&S of urine, stool, sputum, oropharynx, catheter sites, perianal area
  - fever: C&S of all orifices, CXR, start antibiotics
  - platelet and RBC transfusions (irradiated to prevent transfusion-related GVHD) ± EPO
  - prevention and treatment of metabolic abnormalities
    - allopurinol for prevention of hyperuricemia

Prognosis

- achievement of first remission
  - 70-80% if ≤60 yr old, 50% if >60 yr old
  - median survival 12-24 mo
  - 5 yr survival 40%
- prognosis related to cytogenetics (favourable, intermediate or adverse)

Myelodysplastic Syndromes (MDS)

Definition

- heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias
- syndromes defined according to World Health Organization (WHO) classifications (see sidebar)

Pathophysiology

- disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in bone marrow (usually hypercellular)
- intramedullary apoptosis: programmed cell death within bone marrow
  - both processes lead to reduced mature cells in periphery
- <30% develop AML

Risk Factors

- elderly, post-chemotherapy, benzene or radiation exposure
- occurs in 60/100,000 in patients >60 yr old

Clinical Features

- insidious onset: associated with those of pancytopenia
- infections and bleeding out of proportion with peripheral blood counts

2008 WHO MDS Classification

- Refractory cytopenia with unilineage dysplasia
- Refractory anemia
- Refractory neutropenia
- Refractory thrombocytopenia
- Refractory anemia with ringed sideroblasts (RARS)
- Refractory cytopenia with multilineage dysplasia and ringed sideroblasts (RCMD-RS)
- Refractory anemia with excess blasts (RAEB)
- Myelodysplastic syndrome with isolated del (5q)
- Myelodysplasia unclassified (seen in cases of megakaryocyte dysplasia with fibrosis and others)
- Childhood myelodysplastic syndrome

MDS is a cause of macrocytic anemia.

Myelodysplastic Syndromes: ineffective maturation

Myeloproliferative Neoplasms: overproduction of mature cells
Investigations
- diagnosed by:
  - anemia ± thrombocytopenia ± neutropenia
  - CBC and peripheral blood film
  - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
  - WBC: decreased granulocytes and abnormal morphology (e.g. bilobed or unsegmented nuclei = Pelger abnormality)
  - platelets: thrombocytopenia, abnormalities of size and cytoplasm (e.g. giant hypogranular platelets)
- bone marrow aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
  - bone marrow: dysplastic and often normocellular/hypercellular
  - cytogenetics: partial or total loss of chromosomes 5, 7, Y, or trisomy 8

Prognosis
- Revised International Prognostic Scoring System (IPSS-R) uses 5 factors to estimate mean survival:
  - cytology, % bone marrow blasts, hemoglobin, platelets, absolute neutrophil count
  - based on the calculated score, a patient's MDS prognostic risk is "Very Low", "Low", "Intermediate", "High" or "Very High" with a mean survival of 8.7, 5.3, 3.0, 1.6 and 0.8 yr, respectively

Treatment
- low risk of transformation to acute leukemia (IPSS-R Very Low or Low)
  - erythropoietin stimulating agents weekly is first line in reducing transfusion requirements
  - 5q(-) cytogenetic: Revlimid® PO
  - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high risk of transformation to acute leukemia (IPSS-R Intermediate, High or Very High)
  - supportive care
  - stem cell transplantation if age <65 yr
  - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-Azacytidine), histone deacetylase inhibitors

Myeloproliferative Neoplasms (MPNs)

Definition
- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (leading to abnormalities in erythrocytes, platelets and other cells of myeloid lineage)

Epidemiology
- mainly middle-aged and older patients (peak 60-80 yr)

Prognosis
- may develop marrow fibrosis with time
- all disorders may progress to AML

PV = polycythemia vera; CML = chronic myeloid leukemia; IMF = idiopathic myelofibrosis; ET = essential thrombocythemia

Basophilia is uncommon in other medical conditions.
Chronic Myeloid Leukemia (CML)

Definition
- myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

Epidemiology
- occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

Pathophysiology
- Philadelphia chromosome (Ph)
  - translocation between chromosomes 9 and 22
  - the c-abl proto-oncogene is translocated from chromosome 9 to "breakpoint cluster region" (bcr) of chromosome 22 to produce bcr-abl fusion gene, an active tyrosine kinase

Clinical Features
- 3 clinical phases
  - chronic phase: 85% diagnosed here
    - few blasts (<10%) in peripheral film
    - ± slightly elevated eosinophils and basophils
    - no significant symptoms
  - accelerated phase: impaired neutrophil differentiation
    - circulating blasts (10-19%) with increasing peripheral basophils (pruritus)
    - CBC: thrombocytopenia <100 x 10^9/L
    - cytogenetic evidence of clonal evolution
    - worsening constitutional symptoms and splenomegaly (extramedullary hematopoiesis)
  - blast crisis: more aggressive course, blasts fail to differentiate
    - blasts (>20%) in peripheral blood or bone marrow; reflective of acute leukemia (1/3 ALL, 2/3 AML)
- clinical presentation
  - 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
  - nonspecific symptoms
    - fatigue, weight loss, malaise, excessive sweating, fever
  - secondary to splenic involvement
    - early satiety, LUQ pain/fullness, shoulder tip pain (referred)
    - splenomegaly (most common physical finding)
  - anemia
  - bleeding: secondary to platelet dysfunction
    - pruritus, PUD: secondary to increased blood histamine
  - leukostasis, priapism, encephalopathy (rare): secondary to very elevated WBC (rare)

Investigations
- high increase in WBC, decreased/normal RBC, increased/decreased platelets, increased basophils
- WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils
- peripheral blood film
  - leukoerythroid picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
  - presence of different mid-stage progenitor cells differentiates it from AML
- bone marrow
  - myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
- molecular and cytogenetic studies of bone marrow or peripheral blood for Philadelphia chromosome
- abdominal imaging for spleen size

Treatment
- symptomatic:
  - allopurinol and antihistamines
- chronic phase:
  - imatinib mesylate (Gleevec®): inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for bcr-abl
  - if loss of response or intolerance (~25%), trial of 2nd (dasatinib) or 3rd (nilotinib) generation inhibitors
  - interferon-β: may improve response to tyrosine kinase inhibitors
  - hydroxyurea in palliative setting
  - bone marrow transplantation if progression to accelerated or blast phases: CML (curative)
- accelerated phase or blast phase:
  - refer for clinical trial or 2nd/3rd generation TKI and prepare for allogenic stem cell transplant patients, in blast phase typically get standard AML induction
  - stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones

Chronic Myeloproliferative Neoplasias: Six-year follow-up of patients receiving imatinib for the first-line treatment of CML

Leukemia 2009;23:1054-1061

The Randomized Study of Interferon vs. STI571 (IRIS) trial enrolled patients with chronic phase chronic myeloid leukemia (CML-CP) to either imatinib (n=533) or interferon-α (IFN) plus cytarabine (n=553). Assessing the imatinib arm specifically at the sixth year point, there were no reports of disease progression to accelerated phase (AP) or blast crisis (BC), toxicity profile was unchanged, and cytogenetic response rate was 82%. Estimated event-free survival was 83% and rate of freedom from progression to AP and BC was 93%. This 6-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.

Detection of the bcr-abl fusion gene is a diagnostic test for CML (present in over 90% of patients).
• treatment success is monitored based on therapeutic milestones:
  ▪ hematologic: improved WBC and platelet counts, reduced basophils
  ▪ cytogenetic: undetectable Philadelphia-chromosome in the bone marrow
  ▪ molecular: reduction/absence of bcr-abl transcripts in periphery and marrow

**Prognosis**

- survival dependent on response
  ▪ those achieving complete cytogenetic response (CCR) on imatinib by 18 mo of therapy: 6 yr overall survival >90%
  ▪ those who do NOT achieve CCR on imatinib: 6 yr overall survival of 66%
- acute phase (blast crisis – usually within 3-5 yr)
  ▪ 2/3 develop a picture similar to AML
  ▪ unresponsive to remission induction
  ▪ 1/3 develop a picture similar to ALL
  ▪ remission induction (return to chronic phase) achievable

**Polycythemia Vera (PV)**

**Definition**

- stem cell disorder characterized by elevated RBC mass (erythrocytosis) ± increased white cell and platelet production

**Clinical Features**

- symptoms are secondary to high red cell mass and hyperviscosity (see *Erythrocytosis, H6*)
  ▪ bleeding complications: epistaxis, gingival bleeding, ecchymoses and GI bleeding
  ▪ due to platelet abnormalities
  ▪ thrombotic complications: DVT, PE, thrombophlebitis, increased incidence of stroke, MI
  ▪ due to increased blood viscosity, increased platelet number and/or activity
  ▪ erythromelalgia (burning pain in hands and feet and erythema of the skin)
  ▪ due to increased blood viscosity
  ▪ pruritus, especially after warm bath or shower (40%)
  ▪ due to cutaneous mast cell degranulation and histamine release
  ▪ epigastric distress, PUD
  ▪ due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow
  ▪ due to increased blood viscosity
  ▪ gout (hyperuricemia)
  ▪ due to increased cell turnover
  ▪ characteristic physical findings
    ▪ plethora (ruddy complexion) of face (70%), palms
    ▪ splenomegaly (70%), hepatomegaly (40%)

**Investigations**

- see *Erythrocytosis, H6*
- must rule out secondary polycythemia
diagnosis (WHO 2008) requires either both major criteria plus one minor criteria OR the first major criterion plus 2 minor criteria:
  ▪ Major Criteria:  
    1. hemoglobin >18.5 g/dL in men, 16.5 g/dL in women or other evidence of increase red cell volume
    2. presence of JAK2 V617F or other functionally similar mutation such as JAK2 exon 12 mutation
  ▪ Minor Criteria:  
    1. bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic and megakaryocytic proliferation
    2. serum erythropoietin level below the reference range for normal
    3. endogenous erythroid colony formation in vitro

**Treatment**

- phlebotomy to keep hematocrit <45%
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- low-dose Aspirin® (for antithrombotic prophylaxis, will also treat erythromelalgia)
- alloprimol: as needed
- antihistamines: as needed

**Prognosis**

- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)
**Idiopathic Myelofibrosis (IMF)**

**Definition**
- excessive bone marrow fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood and hepatosplenomegaly

**Epidemiology**
- rare, median age at presentation is 65 yr

**Pathophysiology**
- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
  - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
  - leukoerythroblastic blood film (primitive RBCs and WBCs present in blood)
  - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

**Clinical Features**
- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety
